## Chapter 23

# Mirrors and Lenses 

## Quick Quizzes

1. At $C$.

2. (c). Since $n_{\text {water }}>n_{\text {air }}$, the virtual image of the fish formed by refraction at the flat water surface is closer to the surface than is the fish. See Equation 23.9.
3. (a) False. A concave mirror forms an inverted image when the object distance is greater than the focal length.
(b) False. The magnitude of the magnification produced by a concave mirror is greater than 1 if the object distance is less than the radius of curvature.
(c) True.
4. (b). In this case, the index of refraction of the lens material is less than that of the surrounding medium. Under these conditions, a biconvex lens will be divergent.
5. Although a ray diagram only uses 2 or 3 rays (those whose direction is easily determined using only a straight edge), an infinite number of rays leaving the object will always pass through the lens.
6. (a) False. A virtual image is formed on the left side of the lens if $p<f$.
(b) True. An upright, virtual image is formed when $p<f$, while an inverted, real image is formed when $p>f$.
(c) False. A magnified, real image is formed if $2 f>p>f$, and a magnified, virtual image is formed if $p<f$.

## Answers to Even Numbered Conceptual Questions

2. If the finger and the image are at the same distance from you, then they will coincide regardless of what angle you view them from. However, if one is closer than the other, they will appear to coincide only when viewed along the line connecting their positions. When viewed at any angle to this line, the finger and image are seen separately.
3. Chromatic aberration is produced when light passes through a material, as it does when passing through the glass of a lens. A mirror, silvered on its front surface never has light passing through it, so this aberration cannot occur. This is only one of many reasons why large telescopes use mirrors rather than lenses for their primary optical elements.
4. Make the mirror an efficient reflector (shiny); use a parabolic shaped mirror so that it reflects all rays to the image point, even those far from the axis; most important, use a large-diameter mirror in order to collect more solar power.
5. A flat mirror does not reverse left and right. The image of the left hand forms on the left side and the image of the right hand forms on the right side.
6. All objects beneath the stream appear to be closer to the surface than they really are because of refraction. Thus, the pebbles on the bottom of the stream appear to be close to the surface of a shallow stream.
7. An effect similar to a mirage is produced except the "mirage" is seen hovering in the air. Ghost lighthouses in the sky have been seen over bodies of water by this effect.
8. Actually no physics is involved here. The design is chosen so your eyelashes will not brush against the glass as you blink. A reason involving a little physics is that with this design, when you direct your gaze near the outer circumference of the lens you receive a ray that has passed through glass with more nearly parallel surfaces of entry and exit. Then the lens minimally distorts the direction to the object you are looking at.
9. Both words are inverted. However OXIDE looks the same right side up and upside down. LEAD does not.
10. (a) No. The screen is needed to reflect the light toward your eye.
(b) Yes. The light is traveling toward your eye and diverging away from the position of the image, the same as if the object was located at that position.
11. (d). The entire image would appear because any portion of the lens can form the image. The image would be dimmer because the card reduces the light intensity on the screen by $50 \%$.

## Answers to Even Numbered Problems

4. 4.58 m
5. $\quad 7.90 \mathrm{~mm}$
6. (a) 2.22 cm
(b) $\quad M=+10.0$
7. The mirror is concave, with $f \approx 30 \mathrm{~cm}$ and $R \approx 60 \mathrm{~cm}$.
8. (a) 15.0 cm
(b) 60.0 cm
9. $p=+0.708 \mathrm{~cm}$, The image is virtual, upright, and diminished.
10. $\quad 10.0 \mathrm{~cm}$ in front of the mirror
11. 48.0 cm
12. (a) From $p=3.00 \mathrm{~m}$ to $p=0.500 \mathrm{~m}$, the image is real and moves from $q=0.600 \mathrm{~m}$ to $q=+\infty$. From $p=0.500 \mathrm{~m}$ to $p=0$, the image is virtual and moves from $q=-\infty$ to $q=0$.
(b) 0.639 s and 0.782 s
13. (a) 1.50 m
(b) 1.75 m
14. 4.8 cm
15. $\quad 1.50 \mathrm{~cm} / \mathrm{s}$
16. (a) 16.4 cm
(b) 16.4 cm
17. (a) $M=-1.00$ for $p=+24.0 \mathrm{~cm}$,
$M=+1.00$ only if $p=0$ (object against lens)
(b) $M=-1.00$ for $p=-24.0 \mathrm{~cm}$,
$M=+1.00$ only if $p=0$ (object against lens)
18. (a) 5.36 cm
(b) -18.8 cm
(c) virtual, upright, enlarged
(d) A magnifying glass with a focal length 7.50 cm is used to form an upright image of a stamp, enlarged 3.50 times. Find the object distance. Locate and describe the image.
19. $\quad 5.68 \mathrm{~cm}$
20. $M=+3.40$; upright
21. (a) $p=4.00 \mathrm{~m}$ or $p=1.00 \mathrm{~m}$
(b) One image is real, inverted and one-quarter the size of the object. The other image is real, inverted and four times the size of the object.
22. $\quad 9.26 \mathrm{~cm}$ in front of the second lens, $M=+0.370$
23. (a) -11.1 cm
(b) $\quad M=+2.50$
(c) virtual, upright
24. (a) 13.3 cm
(b) $\quad M=-5.90$
(c) inverted, virtual
25. 8.0 cm
26. 25.3 cm behind the mirror, virtual, upright, $M=+8.05$
27. (a) -12.0 cm
(b) -12.0 cm
(c) $\quad-9.00 \mathrm{~cm}$
(d) -6.00 cm
(e) -4.00 cm
28. (a) 10.0 cm in back of the second lens
(b) 2.00 cm , real
(c) 20.0 cm in back of the second lens
29. (a) $p_{1}=0.300 \mathrm{~m}, p_{2}=1.20 \mathrm{~m} \quad$ (b) 0.240 m
(c) real, inverted, and diminished with $M=-0.250$
30. It is real, inverted, and actual size.
31. (a) $4 f / 3$
(b) $3 f / 4$
(c) $-3,+4$
32. +11.7 cm

## Problem Solutions

23.1 If you stand 40 cm in front of the mirror, the time required for light scattered from your face to travel to the mirror and back to your eye is

$$
\Delta t=\frac{2 d}{c}=\frac{2(0.40 \mathrm{~m})}{3.0 \times 10^{8} \mathrm{~m} / \mathrm{s}}=2.7 \times 10^{-9} \mathrm{~s}
$$

Thus, the image you observe shows you $\sim 10^{-9}$ s younger than your current age.
23.2 In the figure at the right, $\theta^{\prime}=\theta$ since they are vertical angles formed by two intersecting straight lines. Their complementary angles are also equal or $\alpha^{\prime}=\alpha$. The right triangles $P Q R$ and $P^{\prime} Q R$ have the common side $Q R$ and are then congruent by the angle-side-angle theorem. Thus, the corresponding sides $P Q$ and $P^{\prime} Q$ are equal, or the image is as far behind the mirror as the object is in front of it.

23.3 (1) The first image in the left-hand mirror is 5.00 ft behind the mirror, or 10.0 ft from the person
(2) The first image in the right-hand mirror serves as an object for the left-hand mirror. It is located 10.0 ft behind the right-hand mirror, which is 25.0 ft from the left-hand mirror. Thus, the second image in the left-hand mirror is 25.0 ft behind the mirror, or 30.0 ft from the person
(3) The first image in the left-hand mirror serves as an object for the right-hand mirror. It is located 20.0 ft in front of the right-hand mirror and forms an image 20.0 ft behind that mirror. This image then serves as an object for the left-hand mirror. The distance from this object to the left-hand mirror is 35.0 ft . Thus, the third image in the left-hand mirror is 35.0 ft behind the mirror, or 40.0 ft from the person
23.4 The virtual image is as far behind the mirror as the choir is in front of the mirror. Thus, the image is 5.30 m behind the mirror.

The image of the choir is

$$
0.800 \mathrm{~m}+5.30 \mathrm{~m}=6.10 \mathrm{~m}
$$

from the organist. Using similar triangles, gives

$$
\frac{h^{\prime}}{0.600 \mathrm{~m}}=\frac{6.10 \mathrm{~m}}{0.800 \mathrm{~m}}
$$

or $\quad h^{\prime}=(0.600 \mathrm{~m})\left(\frac{6.10 \mathrm{~m}}{0.800 \mathrm{~m}}\right)=4.58 \mathrm{~m}$

23.5 Since the mirror is convex, $R<0$. Thus, $R=-0.550 \mathrm{~m}$. With a real object, $p>0$, so $p=+10.0 \mathrm{~m}$. The mirror equation then gives the image distance as

$$
\frac{1}{q}=\frac{2}{R}-\frac{1}{p}=\frac{2}{-0.550 \mathrm{~m}}-\frac{1}{10.0 \mathrm{~m}}, \text { or } q=-0.268 \mathrm{~m}
$$

Thus, the image is virtual and located 0.268 m behind the mirror
The magnification is $M=-\frac{q}{p}=-\frac{-0.268 \mathrm{~m}}{10.0 \mathrm{~m}}=0.0268$

Therefore, the image is upright (since $M>0$ ) and diminished in size (since $|M|<1$ )
23.6 The lateral magnification is given by $M=-q / p$. Therefore, the image distance is

$$
q=-M p=-(0.0130)(30.0 \mathrm{~cm})=-0.390 \mathrm{~cm}
$$

The mirror equation: $\frac{2}{R}=\frac{1}{p}+\frac{1}{q} \quad$ or $\quad R=\frac{2 p q}{p+q}$

$$
\text { gives } \quad R=\frac{2(-0.390 \mathrm{~cm})(30.0 \mathrm{~cm})}{30.0 \mathrm{~cm}-0.390 \mathrm{~cm}}=-0.790 \mathrm{~cm}
$$

The negative sign tells us that the surface is convex. The magnitude of the radius of curvature of the cornea is

$$
|R|=0.790 \mathrm{~cm}=7.90 \mathrm{~mm}
$$

23.7 The radius of curvature of a concave mirror is positive, so $R=+20.0 \mathrm{~cm}$. The mirror equation then gives

$$
\frac{1}{q}=\frac{2}{R}-\frac{1}{p}=\frac{1}{10.0 \mathrm{~cm}}-\frac{1}{p}=\frac{p-10.0 \mathrm{~cm}}{(10.0 \mathrm{~cm}) p}, \text { or } q=\frac{(10.0 \mathrm{~cm}) p}{p-10.0 \mathrm{~cm}}
$$

(a) If $p=40.0 \mathrm{~cm}, q=+13.3 \mathrm{~cm}$ and $M=-\frac{q}{p}=-\frac{13.3 \mathrm{~cm}}{40.0 \mathrm{~cm}}=-0.333$

The image is 13.3 cm in front of the mirror, real, and inverted
(b) When $p=20.0 \mathrm{~cm}, q=+20.0 \mathrm{~cm}$ and $M=-\frac{q}{p}=-\frac{20.0 \mathrm{~cm}}{20.0 \mathrm{~cm}}=-1.00$

The image is 20.0 cm in front of the mirror, real, and inverted
(c) If $p=10.0 \mathrm{~cm}, q=\frac{(10.0 \mathrm{~cm})(10.0 \mathrm{~cm})}{10.0 \mathrm{~cm}-10.0 \mathrm{~cm}} \rightarrow \infty$
and no image is formed. Parallel rays leave the mirror
23.8 (a) Since the object is in front of the mirror, $p>0$. With the image behind the mirror, $q<0$. The mirror equation gives the radius of curvature as

$$
\begin{aligned}
& \frac{2}{R}=\frac{1}{p}+\frac{1}{q}=\frac{1}{1.00 \mathrm{~cm}}-\frac{1}{10.0 \mathrm{~cm}}=\frac{10-1}{10.0 \mathrm{~cm}} \\
& \text { or } R=2\left(\frac{10.0 \mathrm{~cm}}{9}\right)=+2.22 \mathrm{~cm}
\end{aligned}
$$

(b) The magnification is $M=-\frac{q}{p}=-\frac{(-10.0 \mathrm{~cm})}{1.00 \mathrm{~cm}}=+10.0$
23.9 The cylindrical wall is a highly efficient mirror for sound, with radius of curvature, $R=2.50 \mathrm{~m}$.

In a vertical plane the sound disperses as usual but that radiated in a horizontal plane is concentrated in a sound image at distance $q$ from the back of the niche, where

$$
\frac{1}{q}=\frac{2}{R}-\frac{1}{p}=\frac{2}{2.50 \mathrm{~m}}-\frac{1}{2.00 \mathrm{~m}}, \text { which gives } q=3.33 \mathrm{~m}
$$

23.10 The image was initially upright but became inverted when Dina was more than 30 cm from the mirror. From this information, we know that the mirror must be concave because a convex mirror will form only upright, virtual images of real objects.

When the object is located at the focal point of a concave mirror, the rays leaving the mirror are parallel, and no image is formed. Since Dina observed that her image disappeared when she was about 30 cm from the mirror, we know that the focal length must be $f \approx 30 \mathrm{~cm}$. Also, for spherical mirrors, $R=2 f$. Thus, the radius of curvature of this concave mirror must be $R \approx 60 \mathrm{~cm}$.
23.11 The magnified, virtual images formed by a concave mirror are upright, so $M>0$.

Thus, $M=-\frac{q}{p}=\frac{h^{\prime}}{h}=\frac{5.00 \mathrm{~cm}}{2.00 \mathrm{~cm}}=+2.50$, giving

$$
q=-2.50 p=-2.50(+3.00 \mathrm{~cm})=-7.50 \mathrm{~cm}
$$

The mirror equation then gives,

$$
\frac{1}{f}=\frac{2}{R}=\frac{1}{p}+\frac{1}{q}=\frac{1}{3.00 \mathrm{~cm}}-\frac{1}{7.50 \mathrm{~cm}}=\frac{2.50-1}{7.50 \mathrm{~cm}}
$$

or $\quad f=\frac{7.50 \mathrm{~cm}}{1.50}=5.00 \mathrm{~cm}$
23.12 Realize that the magnitude of the radius of curvature, $|R|$, is the same for both sides of the hubcap. For the convex side, $R=-|R|$; and for the concave side, $R=+|R|$. The object distance $p$ is positive (real object) and has the same value in both cases. Also, we write the virtual image distance as $q=-|q|$ in each case. The mirror equation then gives:

For the convex side, $\frac{1}{-|q|}=\frac{2}{-|R|}-\frac{1}{p} \quad$ or $\quad|q|=\frac{|R| p}{|R|+2 p}$
For the concave side, $\frac{1}{-|q|}=\frac{2}{|R|}-\frac{1}{p}$
or $\quad|q|=\frac{|R| p}{|R|-2 p}$
Comparing Equations (1) and (2), we observe that the smaller magnitude image distance, $|q|=10.0 \mathrm{~cm}$, occurs with the convex side of the mirror. Hence, we have

$$
\begin{equation*}
\frac{1}{-10.0 \mathrm{~cm}}=\frac{2}{-|R|}-\frac{1}{p} \tag{3}
\end{equation*}
$$

and for the concave side, $|q|=30.0 \mathrm{~cm}$ gives

$$
\begin{equation*}
\frac{1}{-30.0 \mathrm{~cm}}=\frac{2}{|R|}-\frac{1}{p} \tag{4}
\end{equation*}
$$

(a) Adding Equations (3) and (4) yields $\frac{2}{p}=\frac{3+1}{30.0 \mathrm{~cm}} \quad$ or $\quad p=+15.0 \mathrm{~cm}$
(b) Subtracting (3) from (4) gives $\quad \frac{4}{|R|}=\frac{3-1}{30.0 \mathrm{~cm}} \quad$ or $\quad|R|=60.0 \mathrm{~cm}$
23.13 The image is upright, so $M>0$, and we have

$$
M=-\frac{q}{p}=+2.0, \text { or } q=-2.0 p=-2.0(25 \mathrm{~cm})=-50 \mathrm{~cm}
$$

The radius of curvature is then found to be

$$
\frac{2}{R}=\frac{1}{p}+\frac{1}{q}=\frac{1}{25 \mathrm{~cm}}-\frac{1}{50 \mathrm{~cm}}=\frac{2-1}{50 \mathrm{~cm}}, \text { or } R=2\left(\frac{0.50 \mathrm{~m}}{+1}\right)=1.0 \mathrm{~m}
$$

23.14 The ball is a convex mirror with $R=-\frac{\text { diameter }}{2}=-4.25 \mathrm{~cm}$

Recall that a convex mirror can form only upright virtual images of real objects. Hence, if the image is three-fourths the size of the object, the lateral magnification is

$$
M=-\frac{q}{p}=+\frac{3}{4} \quad \text { which gives } \quad q=-\frac{3}{4} p
$$

The mirror equation then gives

and $\quad p=+\frac{4.25 \mathrm{~cm}}{6}=+0.708 \mathrm{~cm}$

From the ray diagram, observe that the image is virtual, erect, and diminished.
23.15 The focal length of the mirror may be found from the given object and image distances as $1 / f=1 / p+1 / q$, or

$$
f=\frac{p q}{p+q}=\frac{(152 \mathrm{~cm})(18.0 \mathrm{~cm})}{152 \mathrm{~cm}+18.0 \mathrm{~cm}}=+16.1 \mathrm{~cm}
$$

For an upright image twice the size of the object, the magnification is

$$
M=-\frac{q}{p}=+2.00 \text { giving } q=-2.00 p
$$

Then, using the mirror equation again, $1 / p+1 / q=1 / f$ becomes

$$
\begin{aligned}
& \frac{1}{p}+\frac{1}{q}=\frac{1}{p}-\frac{1}{2.00 p}=\frac{2-1}{2.00 p}=\frac{1}{f} \\
& \text { or } \quad p=\frac{f}{2.00}=\frac{16.1 \mathrm{~cm}}{2.00}=8.05 \mathrm{~cm}
\end{aligned}
$$

23.16 A convex mirror $(R<0)$ produces upright, virtual images of real objects.

Thus, $M>0$ giving $M=-\frac{q}{p}=+\frac{1}{3}$, or $q=-\frac{p}{3}$
Then, $\frac{1}{p}+\frac{1}{q}=\frac{2}{R}$ becomes $\frac{1}{p}-\frac{3}{p}=-\frac{2}{10.0 \mathrm{~cm}}$, and yields $p=+10.0 \mathrm{~cm}$

The object is 10.0 cm in front of the mirror
23.17 A convex mirror forms upright, virtual images of objects that are in front of it. Therefore, $M>0$ and we have

$$
M=-\frac{q}{p}=+\frac{1}{2}, \text { or } q=-\frac{p}{2}
$$

Then, $\frac{2}{R}=\frac{1}{p}+\frac{1}{q}=\frac{1}{p}-\frac{2}{p}=-\frac{1}{p}$ or $R=-2 p=-2(10.0 \mathrm{~cm})=-20.0 \mathrm{~cm}$
23.18 The magnified, real images formed by concave mirrors are inverted. Thus, $M<0$ giving

$$
M=-\frac{q}{p}=-4, \text { or } q=4 p
$$

Then, $\frac{2}{R}=\frac{1}{p}+\frac{1}{q}=\frac{1}{p}+\frac{1}{4 p}=\frac{5}{4 p}$ or $R=\frac{8}{5} p=\frac{8}{5}(30.0 \mathrm{~cm})=48.0 \mathrm{~cm}$
23.19 (a) An image formed on a screen is a real image. Thus, the mirror must be concave since, of mirrors, only concave mirrors can form real images of real objects.
(b) The magnified, real images formed by concave mirrors are inverted, so $M<0$ and

$$
M=-\frac{q}{p}=-5, \text { or } p=\frac{q}{5}=\frac{5.0 \mathrm{~m}}{5}=1.0 \mathrm{~m}
$$

The object should be 1.0 m in front of the mirror
( $a$ - revisited) The focal length of the mirror is

$$
\frac{1}{f}=\frac{1}{1.0 \mathrm{~m}}+\frac{1}{5.0 \mathrm{~m}}=\frac{6}{5.0 \mathrm{~m}} \text {, or } f=\frac{5.0 \mathrm{~m}}{6}=0.83 \mathrm{~m}
$$

23.20 (a) From $\frac{1}{p}+\frac{1}{q}=\frac{2}{R}$, we find $q=\frac{R p}{2 p-R}=\frac{(1.00 \mathrm{~m}) p}{2 p-1.00 \mathrm{~m}}$

The table gives the image position at a few critical points in the motion. Between $p=3.00 \mathrm{~m}$ and $p=0.500 \mathrm{~m}$, the real image moves from 0.600 m to infinity. From $p=5.00 \mathrm{~m}$ to $p=0$, the virtual

| $p$ | $q$ |
| :---: | :---: |
| 3.00 m | 0.600 m |
| 0.500 m | $\pm \infty$ |
| 0 | 0 | image moves from negative infinity to 0 .

Note the "jump" in the image position as the ball passes through the focal point of the mirror.
(b) The ball and its image coincide when $p=0$ and when

$$
1 / p+1 / p=2 / p=2 / R, \text { or } p=R=1.00 \mathrm{~m}
$$

From $\Delta y=v_{0 y} t+\frac{1}{2} a_{y} t^{2}$, with $v_{0 y}=0$, the times for the ball to fall from $p=3.00 \mathrm{~m}$ to these positions are found to be

$$
\begin{aligned}
& t=\sqrt{\frac{2(\Delta y)}{a_{y}}}=\sqrt{\frac{2(-2.00 \mathrm{~m})}{-9.80 \mathrm{~m} / \mathrm{s}^{2}}}=0.639 \mathrm{~s} \\
& \text { and } \\
& t=\sqrt{\frac{2(-3.00 \mathrm{~m})}{-9.80 \mathrm{~m} / \mathrm{s}^{2}}}=0.782 \mathrm{~s}
\end{aligned}
$$

23.21 From $\frac{n_{1}}{p}+\frac{n_{2}}{q}=\frac{n_{2}-n_{1}}{R}$, with $R \rightarrow \infty$, the image position is found to be

$$
q=-\frac{n_{2}}{n_{1}} p=-\left(\frac{1.00}{1.309}\right)(50.0 \mathrm{~cm})=-38.2 \mathrm{~cm}
$$

or the virtual image is 38.2 cm below the upper surface of the ice
23.22 For a plane refracting surface $(R \rightarrow \infty)$

$$
\frac{n_{1}}{p}+\frac{n_{2}}{q}=\frac{n_{2}-n_{1}}{R} \text { becomes } q=-\frac{n_{2}}{n_{1}} p
$$

(a) When the pool is full, $p=2.00 \mathrm{~m}$ and

$$
q=-\left(\frac{1.00}{1.333}\right)(2.00 \mathrm{~m})=-1.50 \mathrm{~m}
$$

or the pool appears to be 1.50 m deep
(b) If the pool is half filled, then $p=1.00 \mathrm{~m}$ and $q=-0.750 \mathrm{~m}$. Thus, the bottom of the pool appears to be 0.75 . m below the water surface or 1.75 m below ground level.
23.23 Since the center of curvature of the surface is on the side the light comes from, $R<0$ giving $R=-4.0 \mathrm{~cm}$. Then, $\frac{n_{1}}{p}+\frac{n_{2}}{q}=\frac{n_{2}-n_{1}}{R}$ becomes

$$
\frac{1.00}{q}=\frac{1.00-1.50}{-4.0 \mathrm{~cm}}-\frac{1.50}{4.0 \mathrm{~cm}}, \text { or } q=-4.0 \mathrm{~cm}
$$

Thus, the magnification $M=\frac{h^{\prime}}{h}=-\left(\frac{n_{1}}{n_{2}}\right) \frac{q}{p}$, gives

$$
h^{\prime}=-\left(\frac{n_{1} q}{n_{2} p}\right) h=-\frac{1.50(-4.0 \mathrm{~cm})}{1.00(4.0 \mathrm{~cm})}(2.5 \mathrm{~mm})=3.8 \mathrm{~mm}
$$

23.24 Light scattered from the bottom of the plate undergoes two refractions, once at the top of the plate and once at the top of the water. All surfaces are planes $(R \rightarrow \infty)$, so the image distance for each refraction is $q=-\left(n_{2} / n_{1}\right) p$. At the top of the plate,

$$
q_{1 \mathrm{~B}}=-\left(\frac{n_{\text {water }}}{n_{\text {glass }}}\right) p_{1 \mathrm{~B}}=-\left(\frac{1.333}{1.66}\right)(8.00 \mathrm{~cm})=-6.42 \mathrm{~cm}
$$

or the first image is 6.42 cm below the top of the plate. This image serves as a real object for the refraction at the top of the water, so the final image of the bottom of the plate is formed at

$$
\begin{aligned}
q_{2 \mathrm{~B}} & =-\left(\frac{n_{\text {air }}}{n_{\text {water }}}\right) p_{2 \mathrm{~B}}=-\left(\frac{n_{\text {air }}}{n_{\text {water }}}\right)\left(12.0 \mathrm{~cm}+\left|q_{1 \mathrm{~B}}\right|\right) \\
& =-\left(\frac{1.00}{1.333}\right)(18.4 \mathrm{~cm})=-13.8 \mathrm{~cm} \text { or } 13.8 \mathrm{~cm} \text { below the water surface. }
\end{aligned}
$$

Now, consider light scattered from the top of the plate. It undergoes a single refraction, at the top of the water. This refraction forms an image of the top of the plate at

$$
q_{\mathrm{T}}=-\left(\frac{n_{\text {air }}}{n_{\text {water }}}\right) p_{\mathrm{T}}=-\left(\frac{1.00}{1.333}\right)(12.0 \mathrm{~cm})=-9.00 \mathrm{~cm}
$$

or 9.00 cm below the water surface.
The apparent thickness of the plate is then

$$
\Delta y=\left|q_{2 \mathrm{~B}}\right|-\left|q_{\mathrm{T}}\right|=13.8 \mathrm{~cm}-9.00 \mathrm{~cm}=4.8 \mathrm{~cm}
$$

23.25 As parallel rays from the Sun (object distance, $p \rightarrow \infty$ ) enter the transparent sphere from air $\left(n_{1}=1.00\right)$, the center of curvature of the surface is on the side the light is going toward (back side). Thus, $R>0$. It is observed that a real image is formed on the surface opposite the Sun, giving the image distance as $q=+2 R$.

Then $\frac{n_{1}}{p}+\frac{n_{2}}{q}=\frac{n_{2}-n_{1}}{R} \quad$ becomes $\quad 0+\frac{n}{2 R}=\frac{n-1.00}{R}$
which reduces to $\quad n=2 n-2.00$ and gives $n=2.00$
23.26 The wall of the aquarium is a plane $(R \rightarrow \infty)$ refracting surface separating water $\left(n_{1}=1.333\right)$ and air $\left(n_{2}=1.00\right)$. Thus, $\frac{n_{1}}{p}+\frac{n_{2}}{q}=\frac{n_{2}-n_{1}}{R}$ gives the image position as $q=-\left(\frac{n_{2}}{n_{1}}\right) p=-\frac{p}{1.333}$. When the object position changes by $\Delta p$, the change in the image position is $\Delta q=-\frac{\Delta p}{1.333}$. The apparent speed of the fish is then given by

$$
v_{\text {image }}=\left|\frac{\Delta q}{\Delta t}\right|=\frac{(\Delta p / \Delta t)}{1.333}=\frac{2.00 \mathrm{~cm} / \mathrm{s}}{1.333}=1.50 \mathrm{~cm} / \mathrm{s}
$$

23.27 With $R_{1}=+2.00 \mathrm{~cm}$ and $R_{2}=+2.50 \mathrm{~cm}$, the lens maker's equation gives the focal length as

$$
\begin{aligned}
& \frac{1}{f}=(n-1)\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}\right)=(1.50-1)\left(\frac{1}{2.00 \mathrm{~cm}}-\frac{1}{2.50 \mathrm{~cm}}\right)=0.0500 \mathrm{~cm}^{-1} \\
& \text { or } \quad f
\end{aligned}
$$

23.28 The lens maker's equation is used to compute the focal length in each case.

$$
\text { (a) } \begin{aligned}
\frac{1}{f} & =(n-1)\left[\frac{1}{R_{1}}-\frac{1}{R_{2}}\right] \\
\frac{1}{f} & =(1.44-1)\left[\frac{1}{12.0 \mathrm{~cm}}-\frac{1}{(-18.0 \mathrm{~cm})}\right] \quad f=16.4 \mathrm{~cm}
\end{aligned}
$$

(b) $\frac{1}{f}=(1.44-1)\left[\frac{1}{18.0 \mathrm{~cm}}-\frac{1}{(-12.0 \mathrm{~cm})}\right] \quad f=16.4 \mathrm{~cm}$
23.29 From the thin lens equation, $\frac{1}{p}+\frac{1}{q}=\frac{1}{f}$, the image distance is found to be

$$
q=\frac{f p}{p-f}=\frac{(20.0 \mathrm{~cm}) p}{p-20.0 \mathrm{~cm}}
$$

(a) If $p=40.0 \mathrm{~cm}$, then $q=40.0 \mathrm{~cm}$ and $M=-\frac{q}{p}=-\frac{40.0 \mathrm{~cm}}{40.0 \mathrm{~cm}}=-1.00$

The image is real, inverted, and 40.0 cm beyond the lens
(b) If $p=20.0 \mathrm{~cm}, q \rightarrow \infty$ No image formed. Parallel rays leave the lens.
(c) When $p=10.0 \mathrm{~cm}, q=-20.0 \mathrm{~cm}$ and

$$
M=-\frac{q}{p}=-\frac{(-20.0 \mathrm{~cm})}{10.0 \mathrm{~cm}}=+2.00
$$

The image is virtual, upright, and 20.0 cm in front of the lens
23.30 Since $M=-\frac{q}{p}$, the image distance is $q=-M p$, and the thin lens equation becomes $\frac{1}{p}-\frac{1}{M p}=\frac{1}{f}$ and reduces to $p=\left(1-\frac{1}{M}\right) f$
(a) If $f=12.0 \mathrm{~cm}$, then $p=\left(1-\frac{1}{M}\right)(+12.0 \mathrm{~cm})$

$$
\begin{aligned}
& M=-1.00 \Rightarrow p=+24.0 \mathrm{~cm} \\
& M=+1.00 \Rightarrow p=0 \quad \text { (object is against the lens) }
\end{aligned}
$$

(b) If $f=-12.0 \mathrm{~cm}$, then $p=\left(1-\frac{1}{M}\right)(-12.0 \mathrm{~cm})$

$$
\begin{aligned}
& M=-1.00 \Rightarrow p=-24.0 \mathrm{~cm} \\
& M=+1.00 \Rightarrow p=0 \text { (object is against the lens) }
\end{aligned}
$$

Note that in both cases, $M$ approaches +1.00 only in the limit as $p$ approaches zero. Note also in part (b), the object must be virtual to obtain $M=-1.00$.
23.31 From the thin lens equation, $\frac{1}{p}+\frac{1}{q}=\frac{1}{f}$, the image distance is found to be

$$
q=\frac{f p}{p-f}=\frac{(-20.0 \mathrm{~cm}) p}{p-(-20.0 \mathrm{~cm})}=-\frac{(20.0 \mathrm{~cm}) p}{p+20.0 \mathrm{~cm}}
$$

(a) If $p=40.0 \mathrm{~cm}$, then $q=-13.3 \mathrm{~cm}$ and $M=-\frac{q}{p}=-\frac{(-13.3 \mathrm{~cm})}{40.0 \mathrm{~cm}}=+1 / 3$

The image is
virtual, upright, and 13.3 cm in front of the lens
(b) If $p=20.0 \mathrm{~cm}$, then $q=-10.0 \mathrm{~cm}$ and

$$
M=-\frac{q}{p}=-\frac{(-10.0 \mathrm{~cm})}{20.0 \mathrm{~cm}}=+1 / 2
$$

The image is virtual, upright, and 10.0 cm in front of the lens
(c) When $p=10.0 \mathrm{~cm}, q=-6.67 \mathrm{~cm}$ and $M=-\frac{q}{p}=-\frac{(-6.67 \mathrm{~cm})}{10.0 \mathrm{~cm}}=+2 / 3$

The image is virtual, upright, and 6.67 cm in front of the lens
23.32 Comparing the given equation to the thin lens equation, $\frac{1}{p}+\frac{1}{q}=\frac{1}{f}$, we see that the lens is a convergent lens $(f>0)$ with focal length $f=7.50 \mathrm{~cm}$. Also, the image distance is negative $(q=-3.50 p)$, meaning the image is virtual. The lateral magnification is

$$
M=-\frac{q}{p}=-\frac{-3.50 p}{p}=+3.50 \quad \text { so the image is upright and enlarged. }
$$

(a) Using the information deduced above, the thin lens equation becomes

$$
\frac{1}{p}-\frac{1}{3.50 p}=\frac{1}{7.50 \mathrm{~cm}} \text { giving } p=(7.50 \mathrm{~cm})\left(1-\frac{1}{3.50}\right)=+5.36 \mathrm{~cm}
$$

(b) The image distance is then $\quad q=-3.50(5.36 \mathrm{~cm})=-18.8 \mathrm{~cm}$
(c) See the ray diagram at the right.
(d) A simple magnifier is a device that uses a convergent lens to form an upright, enlarged, virtual image of a real object. One possible problem whose solution would include the given equation is:
"A magnifying glass with focal length 7.50 cm is used to form an upright image of a stamp, enlarged 3.50 times. Find the object distance. Locate and describe the image."
23.33 (a) The real image case is shown in the ray diagram. Notice that $p+q=12.9 \mathrm{~cm}$, or $q=12.9 \mathrm{~cm}-p$. The thin lens equation, with $f=2.44 \mathrm{~cm}$, then gives

$$
\frac{1}{p}+\frac{1}{12.9 \mathrm{~cm}-p}=\frac{1}{2.44 \mathrm{~cm}}
$$

or $p^{2}-(12.9 \mathrm{~cm}) p+31.5 \mathrm{~cm}^{2}=0$

Using the quadratic formula to solve gives

$$
p=9.63 \mathrm{~cm} \text { or } p=3.27 \mathrm{~cm}
$$

Both are valid solutions for the real image case.
(b) The virtual image case is shown in the second diagram. Note that in this case, $q=-(12.9 \mathrm{~cm}+p)$, so the thin lens equation gives

$$
\begin{aligned}
& \frac{1}{p}-\frac{1}{12.9 \mathrm{~cm}+p}=\frac{1}{2.44 \mathrm{~cm}} \\
& \text { or } p^{2}+(12.9 \mathrm{~cm}) p-31.5 \mathrm{~cm}^{2}=0
\end{aligned}
$$

The quadratic formula then gives $p=2.10 \mathrm{~cm}$ or $p=-15.0 \mathrm{~cm}$
Since the object is real, the negative solution must be rejected leaving $p=2.10 \mathrm{~cm}$.
23.34 We must first realize that we are looking at an upright, magnified, virtual image. Thus, we have a real object located between a converging lens and its front-side focal point, so $q<0, p>0$, and $f>0$.

The magnification is $M=-\frac{q}{p}=+2$, giving $q=-2 p$. Then, from the thin lens equation, $\frac{1}{p}-\frac{1}{2 p}=+\frac{1}{2 p}=\frac{1}{f}$ or $f=2 p=2(2.84 \mathrm{~cm})=5.68 \mathrm{~cm}$
23.35 It is desired to form a magnified, real image on the screen using a single thin lens. To do this, a converging lens must be used and the image will be inverted. The magnification then gives

$$
M=\frac{h^{\prime}}{h}=\frac{-1.80 \mathrm{~m}}{24.0 \times 10^{-3} \mathrm{~m}}=-\frac{q}{p}, \text { or } q=75.0 p
$$

Also, we know that $p+q=3.00 \mathrm{~m}$. Therefore, $p+75.0 p=3.00 \mathrm{~m}$ giving
(b) $p=\frac{3.00 \mathrm{~m}}{76.0}=3.95 \times 10^{-2} \mathrm{~m}=39.5 \mathrm{~mm}$
(a) The thin lens equation then gives $\frac{1}{p}+\frac{1}{75.0 p}=\frac{76.0}{75.0 p}=\frac{1}{f}$

$$
\text { or } f=\left(\frac{75.0}{76.0}\right) p=\left(\frac{75.0}{76.0}\right)(39.5 \mathrm{~mm})=39.0 \mathrm{~mm}
$$

23.36 We are given that $f=+12.5 \mathrm{~cm}$ and $q=-30.0 \mathrm{~cm}$. Then, the thin lens equation, $\frac{1}{p}+\frac{1}{q}=\frac{1}{f}$, gives

$$
p=\frac{q f}{q-f}=\frac{(-30.0 \mathrm{~cm})(12.5 \mathrm{~cm})}{-30.0 \mathrm{~cm}-12.5 \mathrm{~cm}}=+8.82 \mathrm{~cm}
$$

and the lateral magnification is $\quad M=-\frac{q}{p}=-\frac{-30.0 \mathrm{~cm}}{8.82 \mathrm{~cm}}=+3.40$
Since $M>0$, the image is upright
23.37 All virtual images formed by diverging lenses are upright images. Thus, $M>0$, and the magnification gives

$$
M=-\frac{q}{p}=+\frac{1}{3}, \text { or } q=-\frac{p}{3}
$$

Then, from the thin lens equation, $\frac{1}{p}-\frac{3}{p}=-\frac{2}{p}=\frac{1}{f}$ or $p=-2 f=2|f|$
The object should be placed at distance $2|f|$ in front of the lens
23.38 (a) The total distance from the object to the real image is the object-to-screen distance, so $p+q=5.00 \mathrm{~m}$ or $q=5.00 \mathrm{~m}-p$. The thin lens equation then becomes

$$
\frac{1}{f}=\frac{1}{p}+\frac{1}{5.00 \mathrm{~m}-p}=\frac{5.00 \mathrm{~m}}{p(5.00 \mathrm{~m}-p)}
$$

or $p^{2}-(5.00 \mathrm{~m}) p+(5.00 \mathrm{~m}) f=0$
With $f=0.800 \mathrm{~m}$, this gives $p^{2}-(5.00 \mathrm{~m}) p+4.00 \mathrm{~m}^{2}=0$ which factors as $(p-4.00 \mathrm{~m})(p-1.00 \mathrm{~m})=0$ with two solutions:

$$
p=4.00 \mathrm{~m} \text { and } p=1.00 \mathrm{~m}
$$

(b) If $p=4.00 \mathrm{~m}$, then $q=1.00 \mathrm{~m}$ and $M=-\frac{q}{p}=-\frac{1.00 \mathrm{~m}}{4.00 \mathrm{~m}}=-\frac{1}{4}$

In this case, the image is real, inverted, and one-quarter the size of the object
If $p=1.00 \mathrm{~m}$, then $q=4.00 \mathrm{~m}$ and $M=-\frac{q}{p}=-\frac{4.00 \mathrm{~m}}{1.00 \mathrm{~m}}=-4$. In this case, the image
is real, inverted, and four times the size of the object
23.39 Since the light rays incident to the first lens are parallel, $p_{1}=\infty$ and the thin lens equation gives $q_{1}=f_{1}=-10.0 \mathrm{~cm}$.

The virtual image formed by the first lens serves as the object for the second lens, so $p_{2}=30.0 \mathrm{~cm}+\left|q_{1}\right|=40.0 \mathrm{~cm}$. If the light rays leaving the second lens are parallel, then $q_{2}=\infty$ and the thin lens equation gives $f_{2}=p_{2}=40.0 \mathrm{~cm}$.
23.40 With $p_{1}=20.0 \mathrm{~cm}$ and $f_{1}=25.0 \mathrm{~cm}$, the thin lens equation gives the position of the image formed by the first lens as

$$
q_{1}=\frac{p_{1} f_{1}}{p_{1}-f_{1}}=\frac{(20.0 \mathrm{~cm})(25.0 \mathrm{~cm})}{20.0 \mathrm{~cm}-25.0 \mathrm{~cm}}=-100 \mathrm{~cm}
$$

and the magnification by this lens is $M_{1}=-\frac{q_{1}}{p_{1}}=-\frac{(-100 \mathrm{~cm})}{20.0 \mathrm{~cm}}=+5.00$
This virtual image serves as the object for the second lens, so the object distance is $p_{2}=25.0 \mathrm{~cm}+\left|q_{1}\right|=125 \mathrm{~cm}$. Then, the thin lens equation gives the final image position as

$$
q_{2}=\frac{p_{2} f_{2}}{p_{2}-f_{2}}=\frac{(125 \mathrm{~cm})(-10.0 \mathrm{~cm})}{125 \mathrm{~cm}-(-10.0 \mathrm{~cm})}=-9.26 \mathrm{~cm}
$$

with a magnification by the second lens of

$$
M_{2}=-\frac{q_{2}}{p_{2}}=-\frac{(-9.26 \mathrm{~cm})}{125 \mathrm{~cm}}=+0.0741
$$

Thus, the final image is located

$$
9.26 \mathrm{~cm} \text { in front of the second lens and }
$$

the overall magnification is $M=M_{1} M_{2}=(+5.00)(+0.0741)=+0.370$
23.41 The thin lens equation gives the image position for the first lens as

$$
q_{1}=\frac{p_{1} f_{1}}{p_{1}-f_{1}}=\frac{(30.0 \mathrm{~cm})(15.0 \mathrm{~cm})}{30.0 \mathrm{~cm}-15.0 \mathrm{~cm}}=+30.0 \mathrm{~cm}
$$

and the magnification by this lens is $M_{1}=-\frac{q_{1}}{p_{1}}=-\frac{30.0 \mathrm{~cm}}{30.0 \mathrm{~cm}}=-1.00$

The real image formed by the first lens serves as the object for the second lens, so $p_{2}=40.0 \mathrm{~cm}-q_{1}=+10.0 \mathrm{~cm}$. Then, the thin lens equation gives

$$
q_{2}=\frac{p_{2} f_{2}}{p_{2}-f_{2}}=\frac{(10.0 \mathrm{~cm})(15.0 \mathrm{~cm})}{10.0 \mathrm{~cm}-15.0 \mathrm{~cm}}=-30.0 \mathrm{~cm}
$$

and the magnification by the second lens is

$$
M_{2}=-\frac{q_{2}}{p_{2}}=-\frac{(-30.0 \mathrm{~cm})}{10.0 \mathrm{~cm}}=+3.00
$$

Thus, the final, virtual image is located 30.0 cm in front of the second lens
and the overall magnification is $M=M_{1} M_{2}=(-1.00)(+3.00)=-3.00$
23.42 (a) With $p_{1}=+15.0 \mathrm{~cm}$, the thin lens equation gives the position of the image formed by the first lens as

$$
q_{1}=\frac{p_{1} f_{1}}{p_{1}-f_{1}}=\frac{(15.0 \mathrm{~cm})(10.0 \mathrm{~cm})}{15.0 \mathrm{~cm}-10.0 \mathrm{~cm}}=+30.0 \mathrm{~cm}
$$

This image serves as the object for the second lens, with an object distance of $p_{2}=10.0 \mathrm{~cm}-q_{1}=10.0 \mathrm{~cm}-30.0 \mathrm{~cm}=-20.0 \mathrm{~cm}$ (a virtual object). If the image formed by this lens is at the position of $O_{1}$, the image distance is

$$
q_{2}=-\left(10.0 \mathrm{~cm}+p_{1}\right)=-(10.0 \mathrm{~cm}+15.0 \mathrm{~cm})=-25.0 \mathrm{~cm}
$$

The thin lens equation then gives the focal length of the second lens as

$$
f_{2}=\frac{p_{2} q_{2}}{p_{2}+q_{2}}=\frac{(-20.0 \mathrm{~cm})(-25.0 \mathrm{~cm})}{-20.0 \mathrm{~cm}-25.0 \mathrm{~cm}}=-11.1 \mathrm{~cm}
$$

(b) The overall magnification is

$$
M=M_{1} M_{2}=\left(-\frac{q_{1}}{p_{1}}\right)\left(-\frac{q_{2}}{p_{2}}\right)=\left(-\frac{30.0 \mathrm{~cm}}{15.0 \mathrm{~cm}}\right)\left[-\frac{(-25.0 \mathrm{~cm})}{(-20.0 \mathrm{~cm})}\right]=+2.50
$$

(c) Since $q_{2}<0$, the final image is virtual ; and since $M>0$, it is upright
23.43 From the thin lens equation, $q_{1}=\frac{p_{1} f_{1}}{p_{1}-f_{1}}=\frac{(4.00 \mathrm{~cm})(8.00 \mathrm{~cm})}{4.00 \mathrm{~cm}-8.00 \mathrm{~cm}}=-8.00 \mathrm{~cm}$

The magnification by the first lens is $M_{1}=-\frac{q_{1}}{p_{1}}=-\frac{(-8.00 \mathrm{~cm})}{4.00 \mathrm{~cm}}=+2.00$
The virtual image formed by the first lens is the object for the second lens, so $p_{2}=6.00 \mathrm{~cm}+\left|q_{1}\right|=+14.0 \mathrm{~cm}$ and the thin lens equation gives

$$
q_{2}=\frac{p_{2} f_{2}}{p_{2}-f_{2}}=\frac{(14.0 \mathrm{~cm})(-16.0 \mathrm{~cm})}{14.0 \mathrm{~cm}-(-16.0 \mathrm{~cm})}=-7.47 \mathrm{~cm}
$$

The magnification by the second lens is $M_{2}=-\frac{q_{2}}{p_{2}}=-\frac{(-7.47 \mathrm{~cm})}{14.0 \mathrm{~cm}}=+0.533$, so the overall magnification is $M=M_{1} M_{2}=(+2.00)(+0.533)=+1.07$

The position of the final image is 7.47 cm in front of the second lens , and its height is $h^{\prime}=M h=(+1.07)(1.00 \mathrm{~cm})=1.07 \mathrm{~cm}$

Since $M>0$, the final image is upright; and since $q_{2}<0$, this image is virtual
23.44 (a) We start with the final image and work backward. From Figure P22.44, observe that $q_{2}=-(50.0 \mathrm{~cm}-31.0 \mathrm{~cm})=-19.0 \mathrm{~cm}$. The thin lens equation
then gives $\quad p_{2}=\frac{q_{2} f_{2}}{q_{2}-f_{2}}=\frac{(-19.0 \mathrm{~cm})(20.0 \mathrm{~cm})}{-19.0 \mathrm{~cm}-20.0 \mathrm{~cm}}=+9.74 \mathrm{~cm}$
The image formed by the first lens serves as the object for the second lens and is located 9.74 cm in front of the second lens.

Thus, $q_{1}=50.0 \mathrm{~cm}-9.74 \mathrm{~cm}=40.3 \mathrm{~cm}$ and the thin lens equation gives

$$
p_{1}=\frac{q_{1} f_{1}}{q_{1}-f_{1}}=\frac{(40.3 \mathrm{~cm})(10.0 \mathrm{~cm})}{40.3 \mathrm{~cm}-10.0 \mathrm{~cm}}=+13.3 \mathrm{~cm}
$$

The original object should be located 13.3 cm in front of the first lens.
(b) The overall magnification is

$$
M=M_{1} M_{2}=\left(-\frac{q_{1}}{p_{1}}\right)\left(-\frac{q_{2}}{p_{2}}\right)=\left(-\frac{40.3 \mathrm{~cm}}{13.3 \mathrm{~cm}}\right)\left(-\frac{(-19.0 \mathrm{~cm})}{9.74 \mathrm{~cm}}\right)=-5.90
$$

(c) Since $M<0$, the final image is inverted;
and since $q_{2}<0$, it is virtual
23.45 Since the final image is to be real and in the film plane, $q_{2}=+d$

Then, the thin lens equation gives $p_{2}=\frac{q_{2} f_{2}}{q_{2}-f_{2}}=\frac{d(13.0 \mathrm{~cm})}{d-13.0 \mathrm{~cm}}$
Note from Figure P23.45 that $d<12.0 \mathrm{~cm}$. The above result then shows that $p_{2}<0$, so the object for the second lens will be a virtual object.

The object of the second lens $\left(L_{2}\right)$ is the image formed by the first lens $\left(L_{1}\right)$, so

$$
q_{1}=(12.0 \mathrm{~cm}-d)-p_{2}=12.0 \mathrm{~cm}-d\left(1+\frac{13.0 \mathrm{~cm}}{d-13.0 \mathrm{~cm}}\right)=12.0 \mathrm{~cm}-\frac{d^{2}}{d-13.0 \mathrm{~cm}}
$$

If $d=5.00 \mathrm{~cm}$, then $q_{1}=+15.1 \mathrm{~cm}$; and when $d=10.0 \mathrm{~cm}, q_{1}=+45.3 \mathrm{~cm}$

From the thin lens equation, $p_{1}=\frac{q_{1} f_{1}}{q_{1}-f_{1}}=\frac{q_{1}(15.0 \mathrm{~cm})}{q_{1}-15.0 \mathrm{~cm}}$
When $q_{1}=+15.1 \mathrm{~cm}(d=5.00 \mathrm{~cm})$, then $p_{1}=1.82 \times 10^{3} \mathrm{~cm}=18.2 \mathrm{~m}$
When $q_{1}=+45.3 \mathrm{~cm}(d=10.0 \mathrm{~cm})$, then $p_{1}=22.4 \mathrm{~cm}=0.224 \mathrm{~m}$
Thus, the range of focal distances for this camera is 0.224 m to 18.2 m
23.46 Consider an object $O_{1}$ at distance $p_{1}$ in front of the first lens. The thin lens equation gives the image position for this lens as $\frac{1}{q_{1}}=\frac{1}{f_{1}}-\frac{1}{p_{1}}$.

The image, $I_{1}$, formed by the first lens serves as the object, $O_{2}$, for the second lens. With the lenses in contact, this will be a virtual object if $I_{1}$ is real and will be a real object if $I_{1}$ is virtual. In either case, if the thicknesses of the lenses may be ignored,

$$
p_{2}=-q_{1} \text { and } \frac{1}{p_{2}}=-\frac{1}{q_{1}}=-\frac{1}{f_{1}}+\frac{1}{p_{1}}
$$

Applying the thin lens equation to the second lens, $\frac{1}{p_{2}}+\frac{1}{q_{2}}=\frac{1}{f_{2}}$ becomes

$$
-\frac{1}{f_{1}}+\frac{1}{p_{1}}+\frac{1}{q_{2}}=\frac{1}{f_{2}} \text { or } \frac{1}{p_{1}}+\frac{1}{q_{2}}=\frac{1}{f_{1}}+\frac{1}{f_{2}}
$$

Observe that this result is a thin lens type equation relating the position of the original object $O_{1}$ and the position of the final image $I_{2}$ formed by this two lens combination. Thus, we see that we may treat two thin lenses in contact as a single lens having a focal length, $f$, given by $\frac{1}{f}=\frac{1}{f_{1}}+\frac{1}{f_{2}}$
23.47 Since $q=+8.00 \mathrm{~cm}$ when $p=+10.0 \mathrm{~cm}$, we find that

$$
\frac{1}{f}=\frac{1}{p}+\frac{1}{q}=\frac{1}{10.0 \mathrm{~cm}}+\frac{1}{8.00 \mathrm{~cm}}=\frac{18.0}{80.0 \mathrm{~cm}}
$$

Then, when $p=20.0 \mathrm{~cm}$,

$$
\frac{1}{q}=\frac{1}{f}-\frac{1}{p}=\frac{18.0}{80.0 \mathrm{~cm}}-\frac{1}{20.0 \mathrm{~cm}}=\frac{18.0-4.00}{80.0 \mathrm{~cm}}=\frac{14.0}{80.0 \mathrm{~cm}}
$$

or $q=\frac{80.0 \mathrm{~cm}}{14.0}=+5.71 \mathrm{~cm}$

Thus, a real image is formed 5.71 cm in front of the mirror
23.48 Applying the thin lens equation to the first lens gives

$$
q_{1}=\frac{p_{1} f_{1}}{p_{1}-f_{1}}=\frac{(12 \mathrm{~cm})(-6.0 \mathrm{~cm})}{12 \mathrm{~cm}-(-6.0 \mathrm{~cm})}=-4.0 \mathrm{~cm}
$$

The virtual image formed by the first lens serves as the object for the second lens. If the image formed by that converging lens is to be located at infinity, the image formed by the diverging lens must be located at the focal point in front of the converging lens.

Thus, $p_{2}=d+\left|q_{1}\right|=f_{2}$ or $d=f_{2}-\left|q_{1}\right|=12 \mathrm{~cm}-4.0 \mathrm{~cm}=8.0 \mathrm{~cm}$
23.49 Since the object is very distant $(p \rightarrow \infty)$, the image distance equals the focal length, or $q=+50.0 \mathrm{~mm}$. Now consider two rays that pass undeviated through the center of the thin lens to opposite sides of the image as shown in the sketch below.

From the sketch, observe that

$$
\tan \left(\frac{\alpha}{2}\right)=\frac{\frac{1}{2}(35.0 \mathrm{~mm})}{50.0 \mathrm{~mm}}=0.350
$$

Thus, the angular width of the image is

$$
\alpha=2 \tan ^{-1}(0.350)=38.6^{\circ}
$$

23.50 Since the object is midway between the lens and mirror, the object distance for the mirror is $p_{1}=+12.5 \mathrm{~cm}$. The mirror equation gives the image position as

$$
\frac{1}{q_{1}}=\frac{2}{R}-\frac{1}{p_{1}}=\frac{2}{20.0 \mathrm{~cm}}-\frac{1}{12.5 \mathrm{~cm}}=\frac{5-4}{50.0 \mathrm{~cm}}=\frac{1}{50.0 \mathrm{~cm}}, \text { or } q_{1}=+50.0 \mathrm{~cm}
$$

This image serves as the object for the lens, so $p_{2}=25.0 \mathrm{~cm}-q_{1}=-25.0 \mathrm{~cm}$. Note that since $p_{2}<0$, this is a virtual object. The thin lens equation gives the image position for the lens as

$$
q_{2}=\frac{p_{2} f_{2}}{p_{2}-f_{2}}=\frac{(-25.0 \mathrm{~cm})(-16.7 \mathrm{~cm})}{-25.0 \mathrm{~cm}-(-16.7 \mathrm{~cm})}=-50.3 \mathrm{~cm}
$$

Since $q_{2}<0$, this is a virtual image that is located 50.3 cm in front of the lens or 25.3 cm behind the mirror . The overall magnification is

$$
M=M_{1} M_{2}=\left(-\frac{q_{1}}{p_{1}}\right)\left(-\frac{q_{2}}{p_{2}}\right)=\left(-\frac{50.0 \mathrm{~cm}}{12.5 \mathrm{~cm}}\right)\left[-\frac{(-50.3 \mathrm{~cm})}{(-25.0 \mathrm{~cm})}\right]=+8.05
$$

Since $M>0$, the final image is upright
23.51 As light passes left-to-right through the lens, the image position is given by

$$
q_{1}=\frac{p_{1} f_{1}}{p_{1}-f_{1}}=\frac{(100 \mathrm{~cm})(80.0 \mathrm{~cm})}{100 \mathrm{~cm}-80.0 \mathrm{~cm}}=+400 \mathrm{~cm}
$$

This image serves as an object for the mirror with an object distance of $p_{2}=100 \mathrm{~cm}-q_{1}=-300 \mathrm{~cm}$ (virtual object). From the mirror equation, the position of the image formed by the mirror is

$$
q_{2}=\frac{p_{2} f_{2}}{p_{2}-f_{2}}=\frac{(-300 \mathrm{~cm})(-50.0 \mathrm{~cm})}{-300 \mathrm{~cm}-(-50.0 \mathrm{~cm})}=-60.0 \mathrm{~cm}
$$

This image is the object for the lens as light now passes through it going right-to-left. The object distance for the lens is $p_{3}=100 \mathrm{~cm}-q_{2}=100 \mathrm{~cm}-(-60.0 \mathrm{~cm})$, or $p_{3}=160 \mathrm{~cm}$. From the thin lens equation,

$$
q_{3}=\frac{p_{3} f_{3}}{p_{3}-f_{3}}=\frac{(160 \mathrm{~cm})(80.0 \mathrm{~cm})}{160 \mathrm{~cm}-80.0 \mathrm{~cm}}=+160 \mathrm{~cm}
$$

Thus, the final image is located 160 cm to the left of the lens
The overall magnification is $M=M_{1} M_{2} M_{3}=\left(-\frac{q_{1}}{p_{1}}\right)\left(-\frac{q_{2}}{p_{2}}\right)\left(-\frac{q_{3}}{p_{3}}\right)$, or

$$
M=\left(-\frac{400 \mathrm{~cm}}{100 \mathrm{~cm}}\right)\left[-\frac{(-60.0 \mathrm{~cm})}{(-300 \mathrm{~cm})}\right]\left(-\frac{160 \mathrm{~cm}}{160 \mathrm{~cm}}\right)=--0.800
$$

Since $M<0$, the final image is inverted
23.52 (a) Using the sign convention from Table 23.2, the radii of curvature of the surfaces are $R_{1}=-15.0 \mathrm{~cm}$ and $R_{2}=+10.0 \mathrm{~cm}$. The lens maker's equation then gives

$$
\frac{1}{f}=(n-1)\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}\right)=(1.50-1)\left(\frac{1}{-15.0 \mathrm{~cm}}-\frac{1}{10.0 \mathrm{~cm}}\right) \text { or } f=-12.0 \mathrm{~cm}
$$

(b) If $p \rightarrow \infty$, then $q=f=-12.0 \mathrm{~cm}$

The thin lens equation gives, $q=\frac{p f}{p-f}=\frac{p(-12.0 \mathrm{~cm})}{p+12.0 \mathrm{~cm}}$ and the following results:
(c) If $p=3|f|=+36.0 \mathrm{~cm}, q=-9.00 \mathrm{~cm}$
(d) If $p=|f|=+12.0 \mathrm{~cm}, q=-6.00 \mathrm{~cm}$
(e) If $p=|f| / 2=+6.00 \mathrm{~cm}, q=-4.00 \mathrm{~cm}$
23.53 A hemisphere is too thick to be described as a thin lens. The light is undeviated on entry into the flat face. We next consider the light's exit from the curved surface, for which $R=-6.00 \mathrm{~cm}$.

The incident rays are parallel, so $p=\infty$.

Then, $\frac{n_{1}}{p}+\frac{n_{2}}{q}=\frac{n_{2}-n_{1}}{R}$ becomes $0+\frac{1.00}{q}=\frac{1.00-1.56}{-6.00 \mathrm{~cm}}$
from which $\quad q=10.7 \mathrm{~cm}$
23.54 (a) The thin lens equation gives the image distance for the first lens as

$$
q_{1}=\frac{p_{1} f_{1}}{p_{1}-f_{1}}=\frac{(40.0 \mathrm{~cm})(20.0 \mathrm{~cm})}{40.0 \mathrm{~cm}-20.0 \mathrm{~cm}}=+40.0 \mathrm{~cm}
$$

The magnification by this lens is then $M_{1}=-\frac{q_{1}}{p_{1}}=-\frac{40.0 \mathrm{~cm}}{40.0 \mathrm{~cm}}=-1.00$

The real image formed by the first lens is the object for the second lens. Thus, $p_{2}=50.0 \mathrm{~cm}-q_{1}=+10.0 \mathrm{~cm}$ and the thin lens equation gives

$$
q_{2}=\frac{p_{2} f_{2}}{p_{2}-f_{2}}=\frac{(10.0 \mathrm{~cm})(5.00 \mathrm{~cm})}{10.0 \mathrm{~cm}-5.00 \mathrm{~cm}}=+10.0 \mathrm{~cm}
$$

The final image is 10.0 cm in back of the second lens
(b) The magnification by the second lens is $M_{2}=-\frac{q_{2}}{p_{2}}=-\frac{10.0 \mathrm{~cm}}{10.0 \mathrm{~cm}}=-1.00$, so the overall magnification is $M=M_{1} M_{2}=(-1.00)(-1.00)=+1.00$. Since this magnification has a value of unity, the final image is the same size as the original object, or $h^{\prime}=M h_{1}=(+1.00)(2.00 \mathrm{~cm})=2.00 \mathrm{~cm}$

The image distance for the second lens is positive, so the final image is $\qquad$
(c) When the two lenses are in contact, the focal length of the combination is

$$
\frac{1}{f}=\frac{1}{f_{1}}+\frac{1}{f_{2}}=\frac{1}{20.0 \mathrm{~cm}}+\frac{1}{5.00 \mathrm{~cm}}, \text { or } f=4.00 \mathrm{~cm}
$$

The image position is then

$$
q=\frac{p f}{p-f}=\frac{(5.00 \mathrm{~cm})(4.00 \mathrm{~cm})}{5.00 \mathrm{~cm}-4.00 \mathrm{~cm}}=+20.0 \mathrm{~cm}
$$

23.55 With light going through the piece of glass from left to right, the radius of the first surface is positive and that of the second surface is negative according to the sign convention of Table 23.2. Thus, $R_{1}=+2.00 \mathrm{~cm}$ and $R_{2}=-4.00 \mathrm{~cm}$.

Applying $\frac{n_{1}}{p}+\frac{n_{2}}{q}=\frac{n_{2}-n_{1}}{R}$ to the first surface gives

$$
\frac{1.00}{1.00 \mathrm{~cm}}+\frac{1.50}{q_{1}}=\frac{1.50-1.00}{+2.00 \mathrm{~cm}}
$$

which yields $q_{1}=-2.00 \mathrm{~cm}$. The first surface forms a virtual image 2.00 cm to the left of that surface and 16.0 cm to the left of the second surface.

The image formed by the first surface is the object for the second surface, so $p_{2}=+16.0 \mathrm{~cm}$ and $\frac{n_{1}}{p}+\frac{n_{2}}{q}=\frac{n_{2}-n_{1}}{R}$ gives

$$
\frac{1.50}{16.0 \mathrm{~cm}}+\frac{1.00}{q_{2}}=\frac{1.00-1.50}{-4.00 \mathrm{~cm}} \text { or } q_{2}=+32.0 \mathrm{~cm}
$$

The final image formed by the piece of glass is a real image located
32.0 cm to the right of the second surface
23.56 In the original configuration,

$$
p_{1}+q_{1}=1.50 \mathrm{~m}
$$

or $\quad q_{1}=1.50 \mathrm{~m}-p_{1}$

In the final configuration, $p_{2}=p_{1}+0.900 \mathrm{~m}$, and

$$
q_{2}=q_{1}-0.900 \mathrm{~m}=1.50 \mathrm{~m}-p_{1}-0.900 \mathrm{~cm}
$$

or $q_{2}=0.600 \mathrm{~m}-p_{1}$
From the thin lens equation $\frac{1}{f}=\frac{1}{p_{1}}+\frac{1}{q_{1}}=\frac{1}{p_{2}}+\frac{1}{q_{2}}$
or $\frac{1}{p_{1}}+\frac{1}{1.50 \mathrm{~m}-p_{1}}=\frac{1}{p_{1}+0.900 \mathrm{~m}}+\frac{1}{0.600 \mathrm{~m}-p_{1}}$

Combining fractions gives

$$
\frac{1.50 \mathrm{~m}}{p_{1}\left(1.50 \mathrm{~m}-p_{1}\right)}=\frac{1.50 \mathrm{~m}}{\left(p_{1}+0.900 \mathrm{~m}\right)\left(0.600 \mathrm{~m}-p_{1}\right)}
$$

or $\quad\left(p_{1}+0.900 \mathrm{~m}\right)\left(0.600 \mathrm{~m}-p_{1}\right)=p_{1}\left(1.50 \mathrm{~m}-p_{1}\right)$
(a) Simplifying yields $0.540 \mathrm{~m}^{2}+(0.600 \mathrm{~m}-0.900 \mathrm{~m}) p_{1}=(1.50 \mathrm{~m}) p_{1}$

$$
\text { or } p_{1}=\frac{0.540 \mathrm{~m}^{2}}{1.80 \mathrm{~m}}=0.300 \mathrm{~m} \text { and } p_{2}=p_{1}+0.900 \mathrm{~m}=1.20 \mathrm{~m}
$$

(b) Then, $q_{1}=1.50 \mathrm{~m}-p_{1}=1.20 \mathrm{~m}$ and the thin lens equation gives

$$
f=\frac{p_{1} q_{1}}{p_{1}+q_{1}}=\frac{(0.300 \mathrm{~m})(1.20 \mathrm{~m})}{1.50 \mathrm{~m}}=0.240 \mathrm{~m}
$$

(c) The second image distance is $q_{2}=0.600 \mathrm{~m}-p_{1}=+0.300 \mathrm{~m}$ and the magnification for this configuration is

$$
M_{2}=-\frac{q_{2}}{p_{2}}=-\frac{0.300 \mathrm{~m}}{1.20 \mathrm{~m}}=-0.250
$$

Thus, the second image is real, inverted, and diminished
23.57 From the thin lens equation, the image distance for the first lens is

$$
q_{1}=\frac{p_{1} f_{1}}{p_{1}-f_{1}}=\frac{(40.0 \mathrm{~cm})(30.0 \mathrm{~cm})}{40.0 \mathrm{~cm}-30.0 \mathrm{~cm}}=+120 \mathrm{~cm}
$$

and the magnification by this lens is $M_{1}=-\frac{q_{1}}{p_{1}}=-\frac{120 \mathrm{~cm}}{40.0 \mathrm{~cm}}=-3.00$
The real image formed by the first lens serves as the object for the second lens, with object distance of $p_{2}=110 \mathrm{~cm}-q_{1}=-10.0 \mathrm{~cm}$ (a virtual object). The thin lens equation gives the image distance for the second lens as

$$
q_{2}=\frac{p_{2} f_{2}}{p_{2}-f_{2}}=\frac{(-10.0 \mathrm{~cm}) f_{2}}{-10.0 \mathrm{~cm}-f_{2}}
$$

(a) If $f_{2}=-20.0 \mathrm{~cm}$, then $q_{2}=+20.0 \mathrm{~cm}$ and the magnification by the second lens is $M_{2}=-q_{2} / p_{2}=-(20.0 \mathrm{~cm}) /(-10.0 \mathrm{~cm})=+2.00$

The final image is located 20.0 cm to the right of the second lens
and the overall magnification is $M=M_{1} M_{2}=(-3.00)(+2.00)=-6.00$
(b) Since $M<0$, the final image is inverted
(c) If $f_{2}=+20.0 \mathrm{~cm}$, then $q_{2}=+6.67 \mathrm{~cm}$
and $\quad M_{2}=-\frac{q_{2}}{p_{2}}=-\frac{6.67 \mathrm{~cm}}{(-10.0 \mathrm{~cm})}=+0.667$
The final image is 6.67 cm to the right of the second lens
and the overall magnification is $M=M_{1} M_{2}=(-3.00)(+0.667)=-2.00$

Since $M<0$, the final image is inverted
23.58 The object is located at the focal point of the upper mirror. Thus, the upper mirror creates an image at infinity (that is, parallel rays leave this mirror). The lower mirror focuses these parallel rays at its focal point, located at the hole in the upper mirror. Thus, the image is real, inverted, and actual size

For the upper mirror:

$$
\frac{1}{p}+\frac{1}{q}=\frac{1}{f} \Rightarrow \frac{1}{7.50 \mathrm{~cm}}+\frac{1}{q_{1}}=\frac{1}{7.50 \mathrm{~cm}}: \quad q_{1}=\infty
$$

For the lower mirror:

$$
\frac{1}{\infty}+\frac{1}{q_{2}}=\frac{1}{7.50 \mathrm{~cm}}: \quad q_{2}=7.50 \mathrm{~cm}
$$

Light directed into the hole in the upper mirror reflects as shown, to behave as if it were reflecting
 from the hole.
23.59 (a) The lens maker's equation, $\frac{1}{f}=(n-1)\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}\right)$, gives

$$
\frac{1}{5.00 \mathrm{~cm}}=(n-1)\left(\frac{1}{9.00 \mathrm{~cm}}-\frac{1}{-11.0 \mathrm{~cm}}\right)
$$

which simplifies to $n=1+\frac{1}{5.00}\left(\frac{99.0}{11.0+9.00}\right)=1.99$
(b) As light passes from left to right through the lens, the thin lens equation gives the image distance as

$$
q_{1}=\frac{p_{1} f}{p_{1}-f}=\frac{(8.00 \mathrm{~cm})(5.00 \mathrm{~cm})}{8.00 \mathrm{~cm}-5.00 \mathrm{~cm}}=+13.3 \mathrm{~cm}
$$

This image formed by the lens serves as an object for the mirror with object distance $p_{2}=20.0 \mathrm{~cm}-q_{1}=+6.67 \mathrm{~cm}$. The mirror equation then gives

$$
q_{2}=\frac{p_{2} R}{2 p_{2}-R}=\frac{(6.67 \mathrm{~cm})(8.00 \mathrm{~cm})}{2(6.67 \mathrm{~cm})-8.00 \mathrm{~cm}}=+10.0 \mathrm{~cm}
$$

This real image, formed 10.0 cm to the left of the mirror, serves as an object for the lens as light passes through it from right to left. The object distance is $p_{3}=20.0 \mathrm{~cm}-q_{2}=+10.0 \mathrm{~cm}$, and the thin lens equation gives

$$
q_{3}=\frac{p_{1} f}{p_{3}-f}=\frac{(10.0 \mathrm{~cm})(5.00 \mathrm{~cm})}{10.0 \mathrm{~cm}-5.00 \mathrm{~cm}}=+10.0 \mathrm{~cm}
$$

The final image is located 10.0 cm to the left of the lens and its overall magnification is

$$
M=M_{1} M_{2} M_{2}=\left(-\frac{q_{1}}{p_{1}}\right)\left(-\frac{q_{2}}{p_{2}}\right)\left(-\frac{q_{3}}{p_{3}}\right)=\left(-\frac{13.3}{8.00}\right)\left(-\frac{10.0}{6.67}\right)\left(-\frac{10.0}{10.0}\right)=-2.50
$$

(c) Since $M<0$, the final image is inverted
23.60 From the thin lens equation, the object distance is $p=\frac{q f}{q-f}$
(a) If $q=+4 f$, then $p=\frac{(4 f) f}{4 f-f}=\frac{4 f}{3}$
(b) When $q=-3 f$, we find $p=\frac{(-3 f) f}{-3 f-f}=\frac{3 f}{4}$
(c) In case (a), $M=-\frac{q}{p}=-\frac{4 f}{4 f / 3}=-3$
and in case (b), $M=-\frac{q}{p}=-\frac{-3 f}{3 f / 4}=+4$
23.61 If $R_{1}=-3.00 \mathrm{~m}$ and $R_{2}=-6.00 \mathrm{~m}$, the focal length is given by

$$
\frac{1}{f}=\left(\frac{n_{1}}{n_{2}}-1\right)\left(\frac{1}{-3.00 \mathrm{~m}}+\frac{1}{6.00 \mathrm{~m}}\right)=\left(\frac{n_{1}-n_{2}}{n_{2}}\right)\left(\frac{-1}{6.00 \mathrm{~m}}\right)
$$

or $\quad f=\frac{(6.00 \mathrm{~m}) n_{2}}{n_{2}-n_{1}}$
(a) If $n_{1}=1.50$ and $n_{2}=1.00$, then $f=\frac{(6.00 \mathrm{~m})(1.00)}{1.00-1.50}=-12.0 \mathrm{~m}$

The thin lens equation gives $q=\frac{p f}{p-f}=\frac{(10.0 \mathrm{~m})(-12.0 \mathrm{~m})}{10.0 \mathrm{~m}+12.0 \mathrm{~m}}=-5.45 \mathrm{~m}$
A virtual image is formed 5.45 m to the left of the lens
(b) If $n_{1}=1.50$ and $n_{2}=1.33$, the focal length is

$$
f=\frac{(6.00 \mathrm{~m})(1.33)}{1.33-1.50}=-46.9 \mathrm{~m}
$$

and $\quad q=\frac{p f}{p-f}=\frac{(10.0 \mathrm{~m})(-46.9 \mathrm{~m})}{10.0 \mathrm{~m}+46.9 \mathrm{~m}}=-8.24 \mathrm{~m}$
The image is located 8.24 m to the left of the lens
(c) When $n_{1}=1.50$ and $n_{2}=2.00, f=\frac{(6.00 \mathrm{~m})(2.00)}{2.00-1.50}=+24.0 \mathrm{~m}$
and $\quad q=\frac{p f}{p-f}=\frac{(10.0 \mathrm{~m})(24.0 \mathrm{~m})}{10.0 \mathrm{~m}-24.0 \mathrm{~m}}=-17.1 \mathrm{~m}$
The image is 17.1 m to the left of the lens
(d) Observe from equation (1) that $f<0$ if $n_{1}>n_{2}$ and $f>0$ when $n_{1}<n_{2}$. Thus, a diverging lens can be changed to converging by surrounding it with a medium whose index of refraction exceeds that of the lens material.
23.62 The inverted image is formed by light that leaves the object and goes directly through the lens, never having reflected from the mirror. For the formation of this inverted image, we have

$$
M=-\frac{q_{1}}{p_{1}}=-1.50 \quad \text { giving } \quad q_{1}=+1.50 p_{1}
$$

The thin lens equation then gives

$$
\frac{1}{p_{1}}+\frac{1}{1.50 p_{1}}=\frac{1}{10.0 \mathrm{~cm}} \quad \text { or } \quad p_{1}=(10.0 \mathrm{~cm})\left(1+\frac{1}{1.50}\right)=16.7 \mathrm{~cm}
$$

The upright image is formed by light that passes through the lens after reflecting from the mirror. The object for the lens in this upright image formation is the image formed by the mirror. In order for the lens to form the upright image at the same location as the inverted image, the image formed by the mirror must be located at the position of the original object (so the object distances, and hence image distances, are the same for both the inverted and upright images formed by the lens). Therefore, the object distance and the image distance for the mirror are equal, and their common value is

$$
q_{\text {mirror }}=p_{\text {mirror }}=40.0 \mathrm{~cm}-p_{1}=40.0 \mathrm{~cm}-16.7 \mathrm{~cm}=+23.3 \mathrm{~cm}
$$

The mirror equation, $\frac{1}{p_{\text {mirror }}}+\frac{1}{q_{\text {mirror }}}=\frac{2}{R}=\frac{1}{f_{\text {mirror }}}$, then gives

$$
\frac{1}{f_{\text {mirror }}}=\frac{1}{23.3 \mathrm{~cm}}+\frac{1}{23.3 \mathrm{~cm}}=\frac{+2}{23.3 \mathrm{~cm}} \quad \text { or } \quad f_{\text {mirror }}=+\frac{23.3 \mathrm{~cm}}{2}=+11.7 \mathrm{~cm}
$$

23.63. (a) The lens maker's equation for a lens made of material with refractive index $n_{1}=1.55$ and immersed in a medium having refractive index $n_{2}$ is

$$
\frac{1}{f}=\left(\frac{n_{1}}{n_{2}}-1\right)\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}\right)=\left(\frac{1.55-n_{2}}{n_{2}}\right)\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}\right)
$$

Thus, when the lens is in air, we have $\frac{1}{f_{\text {air }}}=\left(\frac{1.55-1.00}{1.00}\right)\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}\right)$
and when it is immersed in water, $\quad \frac{1}{f_{\text {water }}}=\left(\frac{1.55-1.33}{1.33}\right)\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}\right)$
Dividing Equation (1) by Equation (2) gives

$$
\frac{f_{\text {water }}}{f_{\text {air }}}=\left(\frac{1.33}{1.00}\right)\left(\frac{1.55-1.00}{1.55-1.33}\right)=1.33\left(\frac{0.55}{0.22}\right)
$$

If $f_{\text {air }}=79.0 \mathrm{~cm}$, the focal length when immersed in water is

$$
f_{\text {water }}=(79.0 \mathrm{~cm}) 1.33\left(\frac{0.55}{0.22}\right)=263 \mathrm{~cm}
$$

(b) The focal length for a mirror is determined by the law of reflection, which is independent of the material of which the mirror is made and of the surrounding medium. Thus, the focal length depends only on the radius of curvature and not on the material making up the mirror or the surrounding medium. This means that, for the mirror,

$$
f_{\text {water }}=f_{\text {air }}=79.0 \mathrm{~cm}
$$
