(End of Simultaneity)

Conclusion: Events that are simultaneous from point of view of some observers will not be simultaneous according to other observers. This is a profound conclusion, and one of the deepest insights into the nature of reality ever discovered! Unexpected feature of time follows directly from constancy of speed of light

Notice: If light speed behaved the same way that motions of ordinary objects did, then platform observers would agree with those on train.

Photon still has to ~~travel~~ travel farther to reach backward president than forwardland president. But in that case light ^{reaching} backward land president gets extra ~~kick~~ due to rain motion: $u_L = c + u$

$$\therefore u \Delta t_B + L = (c + u) \Delta t_B \Rightarrow \Delta t_B = \frac{L}{c}$$

Toward Forwardland president light ~~would~~ speed would be reduced to $u_L = c - u$

$$u \Delta t_F + (c - u) \Delta t_F = L \Rightarrow \Delta t_F = \frac{L}{c}$$

But in real world: Light does not speed up or slow down. Platform observers can justifiably claim that Forwardland pres. did right first.

BH-13

Clocks: Constancy of c requires ^{that} we give up idea that simultaneity is universal. ~~It is~~
 A universal clock ticking off identical seconds on earth, mars, the center of the Galaxy, or M87 giant E galaxy in Virgo cluster does not exist

Rather, observers in relative motion will not agree on which events occur at the same time. Concepts ^{are} rare in every day ~~experience~~ experience. Reason:

$$\frac{\Delta t_B}{\Delta t_F} = \frac{c+u}{c-u} = \frac{1+\frac{u}{c}}{1-\frac{u}{c}}$$

Ⓐ Suppose $u = 10 \text{ mi/hr} \Rightarrow \frac{u}{c} = \frac{10}{670 \times 10^6} \approx 1.5 \times 10^{-8}$

$$\therefore \frac{\Delta t_B}{\Delta t_F} \approx \frac{1+1.5 \times 10^{-8}}{1-1.5 \times 10^{-8}} \approx 1+3 \times 10^{-8}$$

Ⓑ But if $u = 600 \times 10^6 \text{ mi/hr}$, $\frac{u}{c} = \frac{6 \times 10^8}{6.7 \times 10^8} = 0.9$

$$\frac{\Delta t_B}{\Delta t_F} = \frac{1+0.9}{1-0.9} = \frac{1.9}{0.1} \approx 20!$$

| Signal takes 20 times longer to reach backward facing ~~pres.~~ pres. than forward facing president.

BH-14

More on Time

Lot of discussion that ~~was~~ involve abstract definitions
 More concrete definition that suits me:

- Definition of Times
 That which is measured by clocks.
- Definition of Clock:
 Device undergoing repetitive cycles of motion.
- Measure of Time regular
 Count no. of cycles a clock goes through, or fraction of cycles a clock goes through. Good example hands on wrist watch
- Periodic Mechanism responsible for cycles of motion

We need something to drive repetitive motions that do not change from cycle to cycle.

- Pendulum f frequency
- Atomic clocks based well defined transitions ν

• Light Clock:

Since we are interested in how motion affects passage of time, we want to know how motion affects "ticking" of clocks, any clock independent of design.

Simplest conceptual clock is light clock:

[<-previous page](#)

[next page->](#)

(A) Photon bounces back and forth between mirrors

(B) Ticks: Occur every time photon completes one round trip. $\Delta t_{\text{tick}} = \frac{2L}{c}$. If $L = 6''$, $\Delta t_{\text{tick}} = \frac{2 \times 6 \times 2.54}{3 \times 10^{10}} = 10^{-9} \text{ s}$
 about a billion ticks per second.

Moving clocks versus stationary clocks

• Observer at rest w/rt clock: Θ' observer

• Observer who sees clock in motion: Θ observer

Compare whether observers see clocks ticking at same rate. Θ' observer sees vertical motion of photon. But Θ observer photon motion is diagonal, not vertical

Implication: Diagonal path seen by Θ is longer than vertical path seen by Θ' . Since SR tells us c is the same in both cases $\Delta t > \Delta t'$

Quantitative :

$$R = \sqrt{L^2 + u^2 \Delta t^2}$$

Therefore, for Θ observer, time taken to reach top mirror is given by:

$$\Delta t = \frac{R}{c} = \frac{\sqrt{L^2 + u^2 \Delta t^2}}{c}$$

$$c^2 \Delta t^2 = L^2 + u^2 \Delta t^2 \Rightarrow \Delta t^2 (c^2 - u^2) = L^2$$

$$\text{or } \Delta t = \frac{L}{\sqrt{c^2 - u^2}} = \frac{L/c}{\sqrt{1 - (u/c)^2}}$$

For Θ' observer, time taken to reach top mirror is given by $\Delta t' = L/c$

As a result :

$$\Delta t = \frac{\Delta t'}{\sqrt{1 - (u/c)^2}}$$

Time dilation
 $\Delta t > \Delta t'$
 since $u < c$

Observer who sees clock in motion measures longer time intervals than observer at rest w.r.t clock ($\Delta t'$ called proper time)

Mechanical Clocks :

Would ticking of wrist watch slow down in same manner?

(1) Bob's wrist watch to top mirror. Synchronize it with light clock and place it on moving train. If Θ' observer (on train) sees clocks remain in synch, then Θ observer sees them both slow down identically

(2) Only if Θ' sees them fall out of synch will Θ see them slow down differently. For perfect clocks this \rightarrow train motion

But, this would mean uniform motion of train made this happen. Not possible since this would violate SR. Why? Because it would allow \mathcal{O} observer to detect her motion.

Recall: Equivalence between inertial observers implies that observers cannot do experiments, which result in the detection of their motion.

Consequently: clocks in motion observed to tick slower. Implications of Time Dilation according to \mathcal{O} , who sees them in motion, than by \mathcal{O}' who sees them at rest.

Implications of Time Dilation: This "slowing down of time" applies not only to light clocks and wrist watches, but also to time measured by heart beats, lifetime of unstable particles, etc. . . .

Muons: It's a light Fermion (Spin = $1/2$) with mass $m_\mu = 206 m_e$. But it is unstable

Lifetime: $t_\mu = 2.2 \times 10^{-6} \text{ s}$. What does this mean?

Experiment:

Shine a beam of muons with incident rate $\frac{dN_\mu}{dt}$ over

(1) $\frac{dN_\mu(t=0)}{dt}$ = no. of muons per unit time crossing A .

(2) Measure no. of muons ~~over~~ crossing A at time t . Experiments show in limit $v \ll c$

$$\frac{dN_\mu}{dt} = \frac{dN_\mu(t=0)}{dt} \exp\left(-\frac{t}{t_\mu}\right)$$

But when $v \rightarrow c$, say $v = 0.995c$, lifetime according to lab observer, increases

$$t_{\mu}(0) = \frac{t'_{\mu}(0')}{\sqrt{1 - (v/c)^2}} = \frac{t_{\mu}}{\sqrt{1 - (0.995)^2}} = 10 t_{\mu}$$

Cosmic-Ray Muons

$$\text{since } \gamma = \frac{1}{\sqrt{1 - (v/c)^2}} = 10$$

At top of atmosphere muons produced by decay of pion, π^+ , which generated by CR protons

$$\pi^+ \rightarrow \mu^+ + \nu_{\mu}$$

Travel Distance :

(1) Of frame: According to earth observer distance traveled by muon:

$$d = \frac{0.995}{\sqrt{1 - (0.995)^2}} c t_{\mu}(0) \approx c \times 10 \times t_{\mu} = 3 \times 10^8 \times 10 \times 2 \times 10^{-6}$$

$$d = 6 \times 10^5 \text{ m} = 6 \times 10^3 \text{ m} = 6 \text{ km}$$

(2) No time dilation

$$d = c t_{\mu} = 6 \times 10^2 \text{ m}$$

But muons produced at height of $\approx 6 \times 10^3 \text{ m}$. So without time dilation, few would reach earth's surface contrary to observation.

Invariance of the Interval

Let's go back to moving light clock:

Clock Rest Frame

Photon leaves bottom mirror at emission event E , goes upward to top mirror, is reflected back to bottom mirror, where it is recorded at reception event R .

What is the round trip distance traveled by the photon in the clock rest-frame?

$$c \Delta t' = 2L$$

implies that in light-clock rest frame, total distance traveled is

$$\boxed{c \Delta t' = 6\text{m}}$$

1814-20

what is the round-trip time traveled by photon as measured by lab. observer \mathcal{O} ?

Time interval between E & R events in Lab frame: $c\Delta t$

Because of high speed, train containing light mirror, the bottom mirror travels 8m.

In this case $(\frac{c\Delta t}{2})^2 = 4^2 + 3^2 = 25 \text{ m}^2$
 $\Rightarrow (\frac{c\Delta t}{2}) = 5 \text{ m}$ or $c\Delta t = 10 \text{ m}$
 (comparison $u\Delta t/c\Delta t = 8 \text{ m}/10 \text{ m} = 0.8$)

So, there are differences in

(a) Spatial separation and (b) Time separation between events E and R as measured on train and lab.

Interval: But there is a measure of separation that is the same in both frames, i.e., the interval

Interval Definition: $\Delta S^2 = \Delta X^2 - c^2\Delta t^2 = -(c^2\Delta t^2 - \Delta X^2)$

(a) Train: $\Delta X'$ (no motion of mirror); $c\Delta t' = 6 \text{ m}$
 $(\Delta S')^2 = -(6^2 - 0) = -36 \text{ m}^2$

(b) Lab: $\Delta X = 8 \text{ m}$; $c\Delta t = 10 \text{ m}$
 $(\Delta S)^2 = -(10^2 - 8^2) = -(100 - 64) = -36 \text{ m}^2$

Therefore $(\Delta S)^2 = (\Delta S')^2$!

The interval is universal

Interval between 2 spacetime events has same value in all inertial frames that measure these events

Geometrically: $\Delta s^2 = -(2 \times \text{altitude of triangle})^2$

General Form of Interval

In 1-D : $\Delta s^2 = -(c^2 \Delta t^2 - \Delta x^2)$

In 3-D : $\Delta s^2 = -(c^2 \Delta t^2 - \Delta x^2 - \Delta y^2 - \Delta z^2)$

Differential version : $ds^2 = -(c^2 dt^2 - dx^2 - dy^2 - dz^2)$

By requiring ds^2 to have same form and value in all inertial frames, we can derive Lorentz transformations, connecting coordinates of given events, between such frames. Generalizations of Galilean transformations discussed previously.

Geometry

Flat Euclidean : Consider dS^2 which is spatial

part of ds^2

$$dS^2 = dx^2 + dy^2 + dz^2$$

In 2-D

$$dS^2 = dx^2 + dy^2 \quad \text{since } dz = 0$$

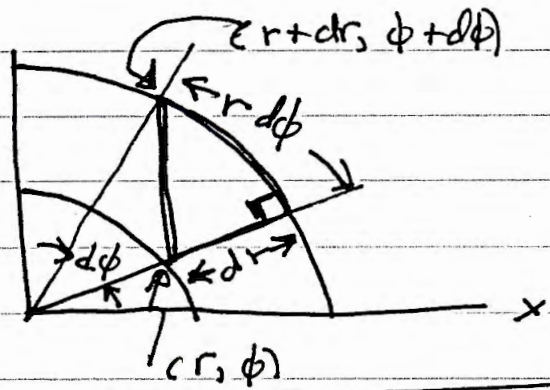

In Cartesian coordinates (x, y) , dS is just distance between points (x, y) and $(x+dx, y+dy)$

$$dS^2 = dx^2 + dy^2$$

Cartesian
(Pythagorean Theorem)

In curvilinear coordinates (r, ϕ) (polar coordinates)

$$dS^2 = dr^2 + (r d\phi)^2$$

dS^2 is independent of choice of coordinates

since $x = r \cos \phi$; $y = r \sin \phi$

$$dx = dr \cos \phi - r \sin \phi d\phi ; dy = dr \sin \phi + r \cos \phi d\phi$$

$$dx^2 + dy^2 = (dr \cos \phi - r \sin \phi d\phi)^2 + (dr \sin \phi + r \cos \phi d\phi)^2$$

$$= (dr \cos \phi)^2 - 2r dr d\phi \cos \phi \sin \phi + (r \sin \phi)^2 d\phi^2$$

$$+ (dr \sin \phi)^2 + 2r dr d\phi \sin \phi \cos \phi + (r \cos \phi)^2 d\phi^2$$

$$dx^2 + dy^2 = dr^2 (\cos^2 \phi + \sin^2 \phi) + r^2 (\sin^2 \phi + \cos^2 \phi) d\phi^2$$

$$dx^2 + dy^2 = dr^2 + r^2 d\phi^2$$

Therefore $dS^2_{\text{Cartesian}} = dS^2_{\text{polar}}$ (same frame, different coordinates)

Principle: Newtonian Physics assumes Space is Euclidean

eg. of free particles in inertial frame: $\frac{d^2x}{dt^2} = \frac{d^2y}{dt^2} = \frac{d^2z}{dt^2} = 0$

[<-previous page](#)

[next page->](#)

3 ways 2 inertial frames can be connected (B-22)

(1) Uniform motion

$$x' = x - ut, \quad y' = y, \quad z' = z, \quad t' = t$$

Galilean

(2) Rigid rotation

(3) displacement same as (1), but replace $d \equiv ut$

$$\begin{aligned} x' &= (\cos \phi) x + (\sin \phi) y \\ y' &= -(\sin \phi) x + (\cos \phi) y \\ z' &= z \\ t' &= t \end{aligned}$$

Invariance

~~Galilean~~ It turns out that these transformations leave Newton's Laws invariant

$$(1) \quad \frac{dx'}{dt'} = \frac{dx}{dt} - u$$

$$\frac{dy'}{dt'} = \frac{dy}{dt}$$

$$\frac{d^2x'}{dt'^2} = \frac{d^2x}{dt^2}$$

$$\frac{d^2y'}{dt'^2} = \frac{d^2y}{dt^2}, \text{ etc.}$$

[<-previous page](#)

Particle accelerations the same in ~~both~~ frames separated by uniform motion [next page->](#)

In rotated frame

$$\frac{dx'}{dt} = \cos\phi \frac{dx}{dt} + \sin\phi \frac{dy}{dt} \quad ; \quad \frac{d^2x'}{dt^2} = \cos\phi \frac{d^2x}{dt^2} + \sin\phi \frac{d^2y}{dt^2}$$
$$\frac{dy'}{dt} = -\sin\phi \frac{dx}{dt} + \cos\phi \frac{dy}{dt} \quad ; \quad \frac{d^2y'}{dt^2} = -\sin\phi \frac{d^2x}{dt^2} + \cos\phi \frac{d^2y}{dt^2}$$

Therefore: if particle is free in unprimed frame, i.e.,

$$\frac{d^2x}{dt^2} = 0 \quad ; \quad \frac{d^2y}{dt^2} = 0$$

then

$$\frac{d^2x'}{dt^2} = 0 \quad ; \quad \frac{d^2y'}{dt^2} = 0$$

Egs. of motion the same in rotated frame

Symmetry of nature holds because Euclidean space shares some symmetries as Newtonian Physics: ds^2 invariant under some Galilean transformation leaving Newton's laws invariant

Two particles at rest in O' frame, ~~are~~ separated by

$$ds^2 = dx'^2 + dy'^2$$

$$x_1 = x'_1 + ut \quad ; \quad x_2 = x'_2 + ut$$

$$dx = x_2 - x_1 = x'_2 - x'_1 + u(t - t) = x'_2 - x'_1$$

$$dy = dy' \quad \Rightarrow \quad ds^2 = dx^2 + dy^2$$

Spacetime Diagrams and lightcones

BH-24

Spacetime diagrams show events in (ct, x) plane

- a single point is an event
- a line $x=x(t)$ or $t=t(x)$ is world line (history) of a particle

Slope $\frac{d(ct)}{dx} = c \frac{dt}{dx} = \frac{1}{(v/c)}$

- Light: $v=c \Rightarrow \frac{d(ct)}{dx} = 1$; slope = 45°

- matter: $v < c \Rightarrow \frac{d(ct)}{dx} > 1$; slope $> 45^\circ$

- Tachyons?: $v > c \Rightarrow \frac{d(ct)}{dx} < 1$; slope $< 45^\circ$

- Particle at rest: $v=0 \Rightarrow \frac{d(ct)}{dx} = \infty$

8-23

Principle of Relativity - relating form of laws of

physics in ~~the~~ inertial frames differing by displacement and rotations is only possible because geometry of Euclidean space shares those symmetries. Laws of physics (in this form) would not be invariant under displacements and rotations if geometry of space were curved.

Geometry:

$$dS^2 = dx^2 + dy^2 + dz^2$$

$dS^2 = dS'^2$ under same transformations that leave Newton's eqs. invariant.

So there is a deep underlying connection between Euclidean Space and Newtonian physics

Back to SR

$$ds^2 = -(cdt)^2 + dx^2 + dy^2 + dz^2$$

We will discuss Lorentz transformations that ~~connect~~ connect

inertial frames and leave ds^2 invariant. But in this case geometry ^{of spacetime} is non-Euclidean because of $-(cdt)^2$ term, but spatially flat

Newtonian: $ds^2 = (cdt)^2 + dx^2 + dy^2 + dz^2$

BH-25

Interval Separation between spacetime events

$$ds^2 = -(c dt)^2 + dx^2 + dy^2 + dz^2$$

1-D For $dy = dz = 0$ $ds^2 = -(c dt)^2 + dx^2$

Lightlike: $dx/dt = \pm c$

Since $c dt = \pm dx$

implies: $ds = 0$

for differential line element separating lightlike events

Interval doesn't look zero. But recall we are not using rules of Euclidean geometry here

$$ds^2 = -c^2 dt^2 + dx^2 \quad (\text{Not } +c^2 dt^2 + dx^2)$$

This is why $ds = 0$

Timelike

$$c dt > dx \Rightarrow ds^2 < 0$$

B4-27

Causality

Light cones define logic of causal connections between events (i.e., points) in spacetime.

Event A can influence

- event B (within its future lightcone)
- " B' (along its " " ")

Event A cannot influence events outside its future lightcone (c)

Event A cannot influence any event in its past (B''), but can be influenced by ~~past~~ events within its past lightcone (B'') or along its past lightcone (B''').

Proper Time & Time Dilation

B-08

Definitions

Clock: A device measuring timelike distances
Ruler: A device measuring spacelike distances

measure of distance along particle worldline:

Define

$$d\tau^2 \equiv -ds^2/c^2$$

Timelike worldlines: $ds^2 < 0 \Rightarrow d\tau^2 > 0$

As a result $d\tau$ is real. This is time measured by clock carried along worldline.

Recall:

$ds^2 = -(c dt')^2 + dx'^2$ where prime is moving coordinate system, i.e., a spacecraft. If clock is at rest w.r.t spacecraft, $dx' = 0$ \rightarrow But $ds^2 = -c^2 d\tau^2$

Therefore $ds^2 = -c^2 dt'^2 \Rightarrow d\tau = dt'$

This is why $d\tau$ is called proper time interval

Lab Frame Again

measured by observer at rest w.r.t clock

ds^2 invariant interval

$$ds^2 = dx^2 + dy^2 + dz^2 - c^2 dt^2 = -c^2 d\tau^2$$

$$\therefore d\tau^2 = dt^2 - \frac{1}{c^2} (dx^2 + dy^2 + dz^2)$$

So, proper time separating events A and B

$$\tau_{AB} = \int_A^B d\tau = \int_{t_A}^{t_B} \sqrt{dt^2 - \frac{(dx^2 + dy^2 + dz^2)}{c^2}}$$

B14-29

$$\tau_{AB} = \int_{t_A}^{t_B} dt \sqrt{1 - \frac{1}{c^2} \left[\left(\frac{dx}{dt} \right)^2 + \left(\frac{dy}{dt} \right)^2 + \left(\frac{dz}{dt} \right)^2 \right]}$$

$$\tau_{AB} = \int_{t_A}^{t_B} dt \sqrt{1 - \left(\frac{v(t)}{c} \right)^2}$$

Proper Time interval τ_{AB} is shorter than Lab time interval $t_B - t_A$ because $|v| < c$.

Differential form $d\tau = dt \sqrt{1 - \left(\frac{v}{c} \right)^2}$

$$c^2 \Delta\tau^2 = c^2 \Delta t^2 - \Delta x^2 \quad (\text{Again } c\Delta\tau \text{ looks like}$$

it is longer than $c\Delta t$. But it is shorter because spacetime geometry is non-Euclidean.

Recap

(1) Connections between Geometry and Physics

• Newtonian Physics: Assumes Space is Euclidean

Physics (a) Galilean Transformations between inertial frames

$$\begin{cases} x' = x - ut \\ y' = y \\ z' = z \\ t' = t \end{cases}$$

Leave Newton's laws invariant, i.e., particle travelling in straight line in one frame does so in all frames. Concept of straight line (shortest distance between 2 points) has meaning only in Euclidean Space

Geometry (b) Galilean Transformations:

Leave Spatial Interval $dS^2 = dx^2 + dy^2 + dz^2$ invariant, i.e., $dS^2 = dS'^2$

assume $dt' = dt$: connection geometry & physics

• Special Relativity

Physics (a) Lorentz Transformations a new (or yet unspecified) transformations between inertial frames leave Maxwell's eqs. for EM waves invariant, so c same in all inertial frames.

(Galilean transforms require speed of light to change, so are rejected by Einstein). Newton's laws change!

Geometry (b) Lorentz transformations:

Leave space-time interval, $ds^2 = -(c dt)^2 + dx^2 + dy^2 + dz^2$, invariant: $ds^2 = ds'^2$

Spacetime Geometry non-Euclidean

BH-296

(2) I introduced concept of spacetime diagrams

- world lines
- events
- light cones divide spacelike from timelike worldlines

(3) I introduced concept of proper time: Time interval in coordinate frame in which clock is at rest: $d\tau^2 = -ds^2/c^2$

$$d\tau = dt \sqrt{1 - (v/c)^2}$$

where dt is time interval in Lab frame that sees clock move with speed v .

3/4-3

Suppose Alice travels at uniform speed $v = \frac{3}{5}c$ until $t_{mid} = \frac{1}{2}(t_1 + t_2)$. She stops instantaneously at t_{mid} , reverses direction and returns to x_p at $t = t_2$, moving again at $v = \frac{3}{5}c$.

Suppose $t_2 - t_1 = 50$ yrs., i.e., Bob has aged 50 years.

$$\Delta\tau_{mid} = \int_{t_1}^{t_{mid}} dt \sqrt{1 - \frac{v^2}{c^2}} = \sqrt{1 - \left(\frac{v}{c}\right)^2} \int_{t_1}^{t_{mid}} dt \quad (\text{since } v = \text{const.})$$

$$\therefore \Delta\tau_{mid} = \sqrt{1 - \left(\frac{v}{c}\right)^2} \left[\frac{1}{2}(t_1 + t_2) - t_1 \right] = \sqrt{1 - \left(\frac{v}{c}\right)^2} \left[\frac{1}{2}(t_2 - t_1) \right]$$

$$\text{or } \Delta\tau_{mid} = \sqrt{1 - \left(\frac{3}{5}\right)^2} \left[\frac{1}{2}(t_2 - t_1) \right] = \frac{4}{5} \cdot \left[\frac{1}{2}(t_2 - t_1) \right]$$

Same result holds from $t_{mid} \rightarrow t_2$
Therefore proper time elapsed for round trip is

$$\Delta\tau_{TOT} = 2 \Delta\tau_{mid} = 2 \times \frac{4}{5} \times \frac{1}{2}(t_2 - t_1)$$

$$\boxed{\Delta\tau_{TOT} = \frac{4}{5}(t_2 - t_1)}$$

Since $t_2 - t_1 = \Delta t_{Bob} = 50$ years, $\left\{ \begin{array}{l} \text{Bob aged by 50 years} \\ \text{Alice " " 40 years} \end{array} \right.$

Note: Situation not symmetric! Even though Alice sees Bob moving, they have different histories. Alice is not an inertial observer, whereas Bob is. Her velocity vector changed and as a result she suffered acceleration whereas Bob is an inertial observer.

[<-previous page](#)

This explains why from Alice's point of view Bob is not younger.

B/14-52

What does spacetime look like to other observers?

Suppose \mathcal{O} observer uses (ct, x) coordinates and another inertial observer \mathcal{O}' uses (ct', x') coordinates where \mathcal{O}' moves along x axis with velocity v wrst \mathcal{O} . What do (ct', x') coordinates go on spacetime diagram for \mathcal{O} ?

Spatial

snapshot at $t = \text{const.}$

Spacetime

ct' axis is locus of all $x'=0$ points (also $y'=z'=0$ points) for all time. ~~trajectory~~

ct' axis is worldline of \mathcal{O}' : at rest in \mathcal{O}' but moves wrst \mathcal{O} .

Recall: $\frac{d(ct')}{dx} = \frac{c}{dx/dt} = \frac{1}{(v/c)}$ is ~~the~~ slope of \mathcal{O}' worldline.

Question: where is x' axis? We need to ^{determine} ~~do~~ it using light trajectories [next page->](#)

BH-30

Twin Paradox

Equation for $\Delta t_{obs} \Rightarrow$ time registered by clock moving between 2 points depends on route traveled even if it returns to same point it started from.

Two ~~twins~~ ^{twins} start out from rest at same spacetime event in an inertial frame. Alice moves away from starting point, but then returns at later time. Each have their own clock.

• Bob's clock: Time elapsed between Alice's departure & return: $t_2 - t_1$

• Alice's clock: Less than this, ^{since} $\sqrt{1 - \frac{v^2}{c^2}} < 1$
Alice ages less than Bob

Numerical Example

returns at midpoint

PRQ 33

Consider O' space time. light mirror again. Photon emitted at event E at $ct' = -a$ reaches x' axis at $t' = 0$ at P . If reflected, it will return to $x' = 0$ at $ct' = +a$ (R).

x' axis defined as locus of events that reflect light emitted at $ct = -a$ and return back at $ct = +a$ for all a . Reflection events synchronized at $t' = 0$. Definition of x' axis.

- ① $E \neq R$ at $(-a, +a)$ along t' axis
- ② Light beam emitted from E at 45°
- ③ Reflected beam must arrive at R along beam with negative 45° slope

④ Intersection is event P

Locus of all P is x' axis ($t' = 0$)
 In both diagrams light travels at 45° , while t & t' axes change slope. Events that were simultaneous in O' are not in O

A & B simultaneous in ct'
 But not in ct

BH-55

Invariance of the interval

Consider 2 events in spacetime diagram. The ~~same~~ coordinate differences separating the events are $\Delta t, \Delta x, \Delta y, \Delta z$.

In that case the interval is given by

$$\Delta S^2 = -(c^2 \Delta t^2 - \Delta x^2 - \Delta y^2 - \Delta z^2)$$

Example: Consider events E & P. world line between these events propagates with speed of light, c.

$$\text{In } \mathcal{O} \quad \frac{\Delta x^2 + \Delta y^2 + \Delta z^2}{\Delta t^2} = c^2 \quad \therefore \Delta S^2 = 0$$

In \mathcal{O}' universality of speed of light implies:

$$\frac{\Delta x'^2 + \Delta y'^2 + \Delta z'^2}{\Delta t'^2} = c^2 \quad \text{separating } \therefore (\Delta S')^2 = 0$$

lightlike events

As a result $\Delta S = \Delta S' = 0$; interval invariant for $\mathcal{O} \rightarrow \mathcal{O}'$ transform

General ΔS : Previously I argued that ΔS was invariant for timelike events E, R on moving light clock which had speed $v < c$. This is a timelike

In fact $(\Delta S)^2 = (\Delta S')^2$ for ~~events~~ intervals connected by any any 2 events, even E, S.

BH-35a

Coordinate Systems + Lorentz transformations

Coordinate Systems look as follows: from \mathcal{O} frame we have -

Figure shows (ct', x') coordinate grid plotted on (ct, x) axes. The (ct', x') coordinates are not orthogonal to each other in Euclidean Geometry of the page. But they are orthogonal in geometry of spacetime.

What are the new transformations that preserve the non-Euclidean ^{interval} $ds^2 = -c^2 dt^2 + dx^2$ of 4D spacetime? Consider analogues of rotation in (ct, x) plane (not x, y plane!!). ~~rotate~~ Analogous to rotation but with hyperbolic trig. because of non-Euclidean nature of spacetime.

Euclidean rotation:
$$\begin{aligned} x' &= (\cos \phi)x + (\sin \phi)y \\ y' &= -(\sin \phi)x + (\cos \phi)y \\ z' &= z \end{aligned}$$
 (mix y, z) } preserve ds^2

S.R. (non-Euclidean) (mix ct, x)

$$\begin{aligned} ct' &= (\cosh \theta)ct - (\sinh \theta)x \\ x' &= -(\sinh \theta)(ct) + (\cosh \theta)x \end{aligned}$$

Preserves ds^2

[<-previous page](#)

$$\cosh \theta = \frac{1}{2}(e^\theta + e^{-\theta}); \quad \sinh \theta = \frac{1}{2}(e^\theta - e^{-\theta})$$

a particle at rest at origin of \mathcal{O}' ; i.e., $x'=0$ in (ct', x') frame has ct' axis as its worldline in (ct, x) frame. Particle moves along x axis with speed $v = \text{const.}$ found by setting $x'=0$

$$\begin{aligned} \text{or } 0 &= -(\sinh \theta)(ct) + (\cosh \theta)x \\ 0 &= -(\sinh \theta)(cdt) + (\cosh \theta)dx \\ \Rightarrow \frac{dx}{dt} &= c \cdot \tanh \theta \quad \text{or } \boxed{v = c \tanh \theta} \end{aligned}$$

Lorentz Transformations

Identity: $\cosh^2 \theta - \sinh^2 \theta = 1$

Divide by $\cosh^2 \theta \Rightarrow 1 - \tanh^2 \theta = 1 / \cosh^2 \theta$

$$\text{or } \cosh^2 \theta = \frac{1}{1 - \tanh^2 \theta} = \frac{1}{(1 - (v/c)^2)}$$

But since $\sinh^2 \theta = \cosh^2 \theta - 1$,

$$\sinh^2 \theta = \frac{1}{1 - (v/c)^2} - 1 = \frac{(v/c)^2}{1 - (v/c)^2}$$

Therefore:

$$x' = -(\sinh \theta)(ct) + (\cosh \theta)x$$

$$x' = -\frac{(v/c)}{\sqrt{1 - (v/c)^2}} (ct) + \frac{1}{\sqrt{1 - (v/c)^2}} (x)$$

$$\boxed{x' = \frac{1}{\sqrt{1 - (v/c)^2}} (x - vt)}$$

$$ct' = (\cosh \theta)(ct) - (\sinh \theta)x$$

$$ct' = \frac{1}{\sqrt{1 - (v/c)^2}} (ct) - \frac{v/c}{\sqrt{1 - (v/c)^2}} x$$

$$\boxed{t = \frac{1}{\sqrt{1 - (v/c)^2}} \left[t' - \frac{vx'}{c^2} \right]}$$

Summary: If $\gamma = \frac{1}{\sqrt{1-(v/c)^2}}$

$$\begin{aligned} x' &= \gamma(x - vt) \\ t' &= \gamma\left(t - \frac{vx}{c^2}\right) \\ y' &= y \\ z' &= z \end{aligned}$$

Lorentz transformations

Here I know \mathcal{O} coordinates.
Find \mathcal{O}' coordinates

Inverse Transformations: But suppose I know \mathcal{O}' coordinates and I want to find \mathcal{O} coordinates
On this case $(t', x', y', z') \rightarrow (t, x, y, z)$

$$\begin{aligned} x &= \gamma(x' + vt') \\ t &= \gamma\left(t' + \frac{vx'}{c^2}\right) \\ y &= y' \\ z &= z' \end{aligned}$$

Both correspond to

Properties of Lorentz Transformations

Limit $v/c \ll 1$, $\gamma \rightarrow 1$:

Lorentz reduces to Galilean transformation

Applications of Lorentz Transformation:

(1) Lorentz length contraction

Suppose rigid rod with length $\Delta x'$ is placed at rest in moving O' frame. What is the length of the rod as measured by O ?

Place clocks along x axis in O frame and measure length simultaneously at both ends, $\Delta t = 0$

$$\left. \begin{array}{l} \text{left end } x_1' = \gamma(x_1 - vt_1) \\ \text{right end } x_2' = \gamma(x_2 - vt_2) \end{array} \right\}$$

$$\Delta x' = x_2' - x_1' = \gamma[x_2 - x_1 - v(t_2 - t_1)]$$

$$\text{But } t_2 - t_1 = 0 \Rightarrow \Delta x' = \gamma \Delta x$$

$$\text{let } \Delta x' = L_0 \text{ (proper length in } O' \text{ frame)}$$

$$\Delta x = L \text{ (measured length in } O \text{ frame)}$$

$$\text{Therefore } \boxed{L = L_0 / \gamma = \sqrt{1 - (v/c)^2} L_0}$$

Length of moving body measured in Lab frame is reduced by factor $\sqrt{1 - (v/c)^2}$

Comment: Lorentz contraction is no "illusion". It is real in the same sense that time dilation is real

Example: \rightarrow

Applications

Muon produced 6 km above earth.

Assume Lab frame is muon rest frame \mathcal{O} . So earth is \mathcal{O}' moving toward muon

Distance between muon and earth:

(1) Earth frame $\Delta x' = 6 \text{ km}$

(2) Muon frame $\Delta x = \frac{\Delta x'}{\gamma} = \sqrt{1 - (v/c)^2} \Delta x'$

\therefore According to muon, time it takes for ground to rush up and hit it is

$$\Delta t = \frac{\Delta x}{0.9995c} \approx \frac{\Delta x}{c} \sqrt{1 - (0.9995)^2} = \frac{1}{10} \frac{\Delta x}{c}$$

$$\Delta t = \frac{1}{10} \times \frac{6 \times 10^5 \text{ m}}{3 \times 10^{10}} = 2 \times 10^{-6} \text{ s}$$

~~Since this is comparable to t_{μ} (muon lifetime)~~

Since this is comparable to t_{μ} (muon lifetime) muon survives long enough to reach earth.

3H-4b

• Klingon events: Great Betwagal

$$x_{GB} = 0; \quad ct_{GB} = 0$$

$$x'_{GB} = \gamma(x_{GB} - \frac{v}{c}(ct_{GB}))$$

$$= \gamma(0 - \frac{v}{c} \times 0)$$

$$\boxed{x'_{GB} = 0}$$

$$ct'_{GB} = \gamma(ct_{GB} - \frac{v}{c}x_{GB}) = \gamma(0 - \frac{v}{c} \times 0)$$

$$\boxed{ct'_{GB} = 0}$$

Interpretation:

In Federation ship coordinate frame

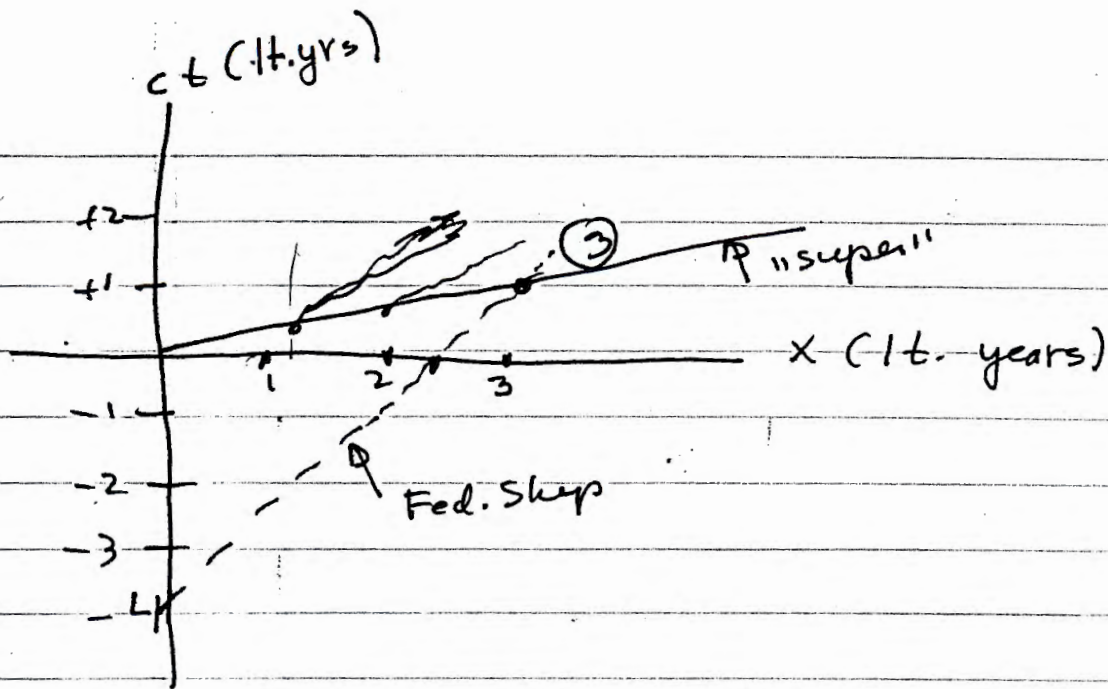

- worldline of super tilts downward to right. Deaths of Fed negotiator occur at $ct'_s = -1$, 1 year before Klingons launch super.
- One could conclude that super moves from Fed ship toward Klingons at $v = 3c$. Yet Feds created no such weapon. Rather they are destroyed by it. Klingons suffer no such damage.

Result • Confusion between cause & effect.

So no object can go with $v > c$. If it did,

we could influence the past

[<-previous page](#)

Klingon Rest Frame:

- Peace treaty of Shalimar signed 4 years before great betrayal
- Peace treaty says: Klingons to stop attacking federation troops in return to access to federation data base
- Federation negotiators leave Shalimar after signing on ship moving at $v=0.6c$
 $\Delta x / \Delta t = 0.6c \Rightarrow \Delta x / ct = 0.6$
- Within 4 years, Klingons use database to construct a projectile, the "super" with $v > c$ velocity. ~~At~~ At $ct=0$, they launch super at $v=3c$ toward Fed ship ($\Delta x / ct = 3$)
- At event (3) Super destroys Fed. Ship
