Chapter 10

1. The problem asks us to assume \( v_{\text{com}} \) and \( \omega \) are constant. For consistency of units, we write

\[
v_{\text{com}} = (85 \text{ mi/h}) \left( \frac{5280 \text{ ft/mi}}{60 \text{ min/h}} \right) = 7480 \text{ ft/min}.
\]

Thus, with \( \Delta x = 60 \text{ ft} \), the time of flight is

\[
t = \frac{\Delta x}{v_{\text{com}}} = \frac{60 \text{ ft}}{7480 \text{ ft/min}} = 0.00802 \text{ min}.
\]

During that time, the angular displacement of a point on the ball’s surface is

\[
\theta = \omega t = (1800 \text{ rev/min}) (0.00802 \text{ min}) \approx 14 \text{ rev}.
\]

2. (a) The second hand of the smoothly running watch turns through \( 2\pi \) radians during 60 s. Thus,

\[
\omega = \frac{2\pi}{60} = 0.105 \text{ rad/s}.
\]

(b) The minute hand of the smoothly running watch turns through \( 2\pi \) radians during 3600 s. Thus,

\[
\omega = \frac{2\pi}{3600} = 1.75 \times 10^{-3} \text{ rad/s}.
\]

(c) The hour hand of the smoothly running 12-hour watch turns through \( 2\pi \) radians during 43200 s. Thus,

\[
\omega = \frac{2\pi}{43200} = 1.45 \times 10^{-4} \text{ rad/s}.
\]

3. The falling is the type of constant-acceleration motion you had in Chapter 2. The time it takes for the buttered toast to hit the floor is

\[
\Delta t = \sqrt{\frac{2h}{g}} = \sqrt{\frac{2(0.76 \text{ m})}{9.8 \text{ m/s}^2}} = 0.394 \text{ s}.
\]

(a) The smallest angle turned for the toast to land butter-side down is \( \Delta \theta_{\text{min}} = 0.25 \text{ rev} = \pi / 2 \text{ rad} \). This corresponds to an angular speed of
(b) The largest angle (less than 1 revolution) turned for the toast to land butter-side down is \( \Delta \theta_{\text{max}} = 0.75 \text{ rev} = \frac{3\pi}{2} \text{ rad} \). This corresponds to an angular speed of

\[
\omega_{\text{max}} = \frac{\Delta \theta_{\text{max}}}{\Delta t} = \frac{3\pi/2 \text{ rad}}{0.394 \text{ s}} = 12.0 \text{ rad/s}
\]

4. If we make the units explicit, the function is

\[
\theta = 2.0 \text{ rad} + \left(4.0 \text{ rad/s}^2\right)t^2 + \left(2.0 \text{ rad/s}^3\right)t^3
\]

but in some places we will proceed as indicated in the problem—by letting these units be understood.

(a) We evaluate the function \( \theta \) at \( t = 0 \) to obtain \( \theta_0 = 2.0 \text{ rad} \).

(b) The angular velocity as a function of time is given by Eq. 10-6:

\[
\omega = \frac{d\theta}{dt} = \left(8.0 \text{ rad/s}^2\right)t + \left(6.0 \text{ rad/s}^3\right)t^2
\]

which we evaluate at \( t = 0 \) to obtain \( \omega_0 = 0 \).

(c) For \( t = 4.0 \text{ s} \), the function found in the previous part is

\[
\omega_t = (8.0)(4.0) + (6.0)(4.0)^2 = 128 \text{ rad/s}
\]

If we round this to two figures, we obtain \( \omega_t \approx 1.3 \times 10^2 \text{ rad/s} \).

(d) The angular acceleration as a function of time is given by Eq. 10-8:

\[
\alpha = \frac{d\omega}{dt} = 8.0 \text{ rad/s}^2 + \left(12 \text{ rad/s}^3\right)t
\]

which yields \( \alpha_2 = 8.0 + (12)(2.0) = 32 \text{ rad/s}^2 \) at \( t = 2.0 \text{ s} \).

(e) The angular acceleration, given by the function obtained in the previous part, depends on time; it is not constant.

5. Applying Eq. 2-15 to the vertical axis (with +\( y \) downward) we obtain the free-fall time:
\[ \Delta y = v_0 y + \frac{1}{2} g t^2 \Rightarrow t = \sqrt{\frac{2(10 \text{ m})}{9.8 \text{ m/s}^2}} = 1.4 \text{ s}. \]

Thus, by Eq. 10-5, the magnitude of the average angular velocity is

\[ \omega_{\text{avg}} = \frac{(2.5 \text{ rev})(2\pi \text{ rad/rev})}{1.4 \text{ s}} = 11 \text{ rad/s}. \]

6. If we make the units explicit, the function is

\[ \theta = (4.0 \text{ rad/s})t - (3.0 \text{ rad/s}^2)t^2 + (1.0 \text{ rad/s}^3)t^3 \]

but generally we will proceed as shown in the problem—letting these units be understood. Also, in our manipulations we will generally not display the coefficients with their proper number of significant figures.

(a) Equation 10-6 leads to

\[ \omega = \frac{d}{dt}(4t - 3t^2 + t^3) = 4 - 6t + 3t^2. \]

Evaluating this at \( t = 2 \text{ s} \) yields \( \omega_2 = 4.0 \text{ rad/s} \).

(b) Evaluating the expression in part (a) at \( t = 4 \text{ s} \) gives \( \omega_4 = 28 \text{ rad/s} \).

(c) Consequently, Eq. 10-7 gives

\[ \alpha_{\text{avg}} = \frac{\omega_4 - \omega_2}{4 - 2} = 12 \text{ rad/s}^2. \]

(d) And Eq. 10-8 gives

\[ \alpha = \frac{d\omega}{dt} = \frac{d}{dt}(4 - 6t + 3t^2) = -6 + 6t. \]

Evaluating this at \( t = 2 \text{ s} \) produces \( \alpha_2 = 6.0 \text{ rad/s}^2 \).

(e) Evaluating the expression in part (d) at \( t = 4 \text{ s} \) yields \( \alpha_4 = 18 \text{ rad/s}^2 \). We note that our answer for \( \alpha_{\text{avg}} \) does turn out to be the arithmetic average of \( \alpha_2 \) and \( \alpha_4 \) but point out that this will not always be the case.

7. (a) To avoid touching the spokes, the arrow must go through the wheel in not more than

\[ \Delta t = \frac{1/8 \text{ rev}}{2.5 \text{ rev/s}} = 0.050 \text{ s}. \]
The minimum speed of the arrow is then \( v_{\text{min}} = \frac{20 \text{ cm}}{0.050 \text{ s}} = 400 \text{ cm/s} = 4.0 \text{ m/s}. \)

(b) No—there is no dependence on radial position in the above computation.

8. (a) We integrate (with respect to time) the \( \alpha = 6.0t^4 - 4.0t^2 \) expression, taking into account that the initial angular velocity is 2.0 rad/s. The result is

\[
\omega = 1.2 t^5 - 1.33 t^3 + 2.0.
\]

(b) Integrating again (and keeping in mind that \( \theta_0 = 1 \)) we get

\[
\theta = 0.20t^6 - 0.33 t^4 + 2.0 t + 1.0.
\]

9. (a) With \( \omega = 0 \) and \( \alpha = -4.2 \text{ rad/s}^2 \), Eq. 10-12 yields \( t = -\omega / \alpha = 3.00 \text{ s} \).

(b) Eq. 10-4 gives \( \theta - \theta_0 = - \omega \theta / 2\alpha = 18.9 \text{ rad} \).

10. We assume the sense of rotation is positive, which (since it starts from rest) means all quantities (angular displacements, accelerations, etc.) are positive-valued.

(a) The angular acceleration satisfies Eq. 10-13:

\[
25 \text{ rad} = \frac{1}{2} \alpha (5.0 \text{ s})^2 \quad \Rightarrow \quad \alpha = 2.0 \text{ rad/s}^2.
\]

(b) The average angular velocity is given by Eq. 10-5:

\[
\omega_{\text{avg}} = \frac{\Delta \theta}{\Delta t} = \frac{25 \text{ rad}}{5.0 \text{ s}} = 5.0 \text{ rad/s}.
\]

(c) Using Eq. 10-12, the instantaneous angular velocity at \( t = 5.0 \text{ s} \) is

\[
\omega = (2.0 \text{ rad/s}^2) (5.0 \text{ s}) = 10 \text{ rad/s}.
\]

(d) According to Eq. 10-13, the angular displacement at \( t = 10 \text{ s} \) is

\[
\theta = \omega_0 + \frac{1}{2} \alpha t^2 = 0 + \frac{1}{2} (2.0 \text{ rad/s}^2) (10 \text{ s})^2 = 100 \text{ rad}.
\]

Thus, the displacement between \( t = 5 \text{ s} \) and \( t = 10 \text{ s} \) is \( \Delta \theta = 100 \text{ rad} - 25 \text{ rad} = 75 \text{ rad} \).
11. We assume the sense of initial rotation is positive. Then, with $\omega_0 = +120 \text{ rad/s}$ and $\omega = 0$ (since it stops at time $t$), our angular acceleration (‘‘deceleration’’) will be negative-valued: $\alpha = -4.0 \text{ rad/s}^2$.

(a) We apply Eq. 10-12 to obtain $t$.

$$\omega = \omega_0 + \alpha t \implies t = \frac{0 - 120 \text{ rad/s}}{-4.0 \text{ rad/s}^2} = 30 \text{ s}.$$

(b) And Eq. 10-15 gives

$$\theta = \frac{1}{2} (\omega_0 + \omega) t = \frac{1}{2} (120 \text{ rad/s} + 0)(30 \text{ s}) = 1.8 \times 10^3 \text{ rad}.$$

Alternatively, Eq. 10-14 could be used if it is desired to only use the given information (as opposed to using the result from part (a)) in obtaining $\theta$. If using the result of part (a) is acceptable, then any angular equation in Table 10-1 (except Eq. 10-12) can be used to find $\theta$.

12. (a) We assume the sense of rotation is positive. Applying Eq. 10-12, we obtain

$$\omega = \omega_0 + \alpha t \implies \alpha = \frac{(3000 - 1200) \text{ rev/min}}{(12/60) \text{ min}} = 9.0 \times 10^3 \text{ rev/min}^2.$$

(b) And Eq. 10-15 gives

$$\theta = \frac{1}{2} (\omega_0 + \omega) t = \frac{1}{2} (1200 \text{ rev/min} + 3000 \text{ rev/min}) \left(\frac{12}{60} \text{ min}\right) = 4.2 \times 10^2 \text{ rev}.$$

13. The wheel has angular velocity $\omega_0 = +1.5 \text{ rad/s} = +0.239 \text{ rev/s}$ at $t = 0$, and has constant value of angular acceleration $\alpha < 0$, which indicates our choice for positive sense of rotation. At $t_1$ its angular displacement (relative to its orientation at $t = 0$) is $\theta_1 = +20 \text{ rev}$, and at $t_2$ its angular displacement is $\theta_2 = +40 \text{ rev}$ and its angular velocity is $\omega_2 = 0$.

(a) We obtain $t_2$ using Eq. 10-15:

$$\theta_2 = \frac{1}{2} (\omega_0 + \omega_2) t_2 \implies t_2 = \frac{2(40 \text{ rev})}{0.239 \text{ rev/s}} = 335 \text{ s}$$

which we round off to $t_2 \approx 3.4 \times 10^2 \text{ s}$.

(b) Any equation in Table 10-1 involving $\alpha$ can be used to find the angular acceleration; we select Eq. 10-16.
\[
\theta_2 = \omega_2 t_2 - \frac{1}{2} \alpha t_2^2 \quad \Rightarrow \quad \alpha = \frac{-2(40 \text{ rev})}{(335 \text{ s})^2} = -7.12 \times 10^{-4} \text{ rev/s}^2
\]

which we convert to \( \alpha = -4.5 \times 10^{-3} \text{ rad/s}^2 \).

(c) Using \( \theta = \omega_0 t + \frac{1}{2} \alpha t^2 \) (Eq. 10-13) and the quadratic formula, we have

\[
t_1 = \frac{-\omega_0 \pm \sqrt{\omega_0^2 + 2\theta_1 \alpha}}{\alpha} = \frac{-(0.239 \text{ rev/s}) \pm \sqrt{(0.239 \text{ rev/s})^2 + 2(20 \text{ rev})(-7.12 \times 10^{-4} \text{ rev/s}^2)}}{-7.12 \times 10^{-4} \text{ rev/s}^2}
\]

which yields two positive roots: 98 s and 572 s. Since the question makes sense only if \( t_1 < t_2 \) we conclude the correct result is \( t_1 = 98 \text{ s} \).

14. The wheel starts turning from rest (\( \omega_0 = 0 \)) at \( t = 0 \), and accelerates uniformly at \( \alpha > 0 \), which makes our choice for positive sense of rotation. At \( t_1 \) its angular velocity is \( \omega_1 = +10 \text{ rev/s} \), and at \( t_2 \) its angular velocity is \( \omega_2 = +15 \text{ rev/s} \). Between \( t_1 \) and \( t_2 \) it turns through \( \Delta \theta = 60 \text{ rev} \), where \( t_2 - t_1 = \Delta t \).

(a) We find \( \alpha \) using Eq. 10-14:

\[
\omega_2^2 = \omega_1^2 + 2\alpha \Delta \theta \quad \Rightarrow \quad \alpha = \frac{(15 \text{ rev/s})^2 - (10 \text{ rev/s})^2}{2(60 \text{ rev})} = 1.04 \text{ rev/s}^2
\]

which we round off to 1.0 \text{ rev/s}^2.

(b) We find \( \Delta t \) using Eq. 10-15: \( \Delta \theta = \frac{1}{2} (\omega_1 + \omega_2) \Delta t \Rightarrow \Delta t = \frac{2(60 \text{ rev})}{10 \text{ rev/s} + 15 \text{ rev/s}} = 4.8 \text{ s} \).

(c) We obtain \( t_1 \) using Eq. 10-12: \( \omega_1 = \omega_0 + \alpha t_1 \Rightarrow t_1 = \frac{10 \text{ rev/s}}{1.04 \text{ rev/s}^2} = 9.6 \text{ s} \).

(d) Any equation in Table 10-1 involving \( \theta \) can be used to find \( \theta_1 \) (the angular displacement during \( 0 \leq t \leq t_1 \)); we select Eq. 10-14.

\[
\omega_1^2 = \omega_0^2 + 2\alpha \theta_1 \Rightarrow \theta_1 = \frac{(10 \text{ rev/s})^2}{2(1.04 \text{ rev/s}^2)} = 48 \text{ rev}.
\]

15. THINK We have a wheel rotating with constant angular acceleration. We can apply the equations given in Table 10-1 to analyze the motion.

EXPRESS Since the wheel starts from rest, its angular displacement as a function of time is given by \( \theta = \frac{1}{2} \alpha t^2 \). We take \( t_1 \) to be the start time of the interval so that \( t_2 = t_1 + 4.0 \text{ s} \). The corresponding angular displacements at these times are
\[ \theta_1 = \frac{1}{2} \alpha t_1^2, \quad \theta_2 = \frac{1}{2} \alpha t_2^2 \]

Given \( \Delta \theta = \theta_2 - \theta_1 \), we can solve for \( t_1 \), which tells us how long the wheel has been in motion up to the beginning of the 4.0 s-interval.

**ANALYZE** The above expressions can be combined to give

\[ \Delta \theta = \theta_2 - \theta_1 = \frac{1}{2} \alpha (t_2^2 - t_1^2) = \frac{1}{2} \alpha (t_2 + t_1)(t_2 - t_1) \]

With \( \Delta \theta = 120 \text{ rad} \), \( \alpha = 3.0 \text{ rad/s}^2 \), and \( t_2 - t_1 = 4.0 \text{ s} \), we obtain

\[ t_2 + t_1 = \frac{2(\Delta \theta)}{\alpha(t_2 - t_1)} = \frac{2(120 \text{ rad})}{(3.0 \text{ rad/s}^2)(4.0 \text{ s})} = 20 \text{ s}, \]

which can be further solved to give \( t_2 = 12.0 \text{ s} \) and \( t_1 = 8.0 \text{ s} \). So, the wheel started from rest 8.0 s before the start of the described 4.0 s interval.

**LEARN** We can readily verify the results by calculating \( \theta_1 \) and \( \theta_2 \) explicitly:

\[ \theta_1 = \frac{1}{2} \alpha t_1^2 = \frac{1}{2} (3.0 \text{ rad/s}^2)(8.0 \text{ s})^2 = 96 \text{ rad} \]
\[ \theta_2 = \frac{1}{2} \alpha t_2^2 = \frac{1}{2} (3.0 \text{ rad/s}^2)(12.0 \text{ s})^2 = 216 \text{ rad}. \]

Indeed the difference is \( \Delta \theta = \theta_2 - \theta_1 = 120 \text{ rad} \).

16. (a) Eq. 10-13 gives

\[ \theta - \theta_o = \omega_o t + \frac{1}{2} \alpha t^2 = 0 + \frac{1}{2} (1.5 \text{ rad/s}^2)t_1^2 \]

where \( \theta - \theta_o = (2 \text{ rev})(2\pi \text{ rad/rev}) \). Therefore, \( t_1 = 4.09 \text{ s} \).

(b) We can find the time to go through a full 4 rev (using the same equation to solve for a new time \( t_2 \)) and then subtract the result of part (a) for \( t_1 \) in order to find this answer.

\( (4 \text{ rev})(2\pi \text{ rad/rev}) = 0 + \frac{1}{2} (1.5 \text{ rad/s}^2)t_2^2 \Rightarrow t_2 = 5.789 \text{ s} \).

Thus, the answer is 5.789 s – 4.093 s ≈ 1.70 s.

17. The problem has (implicitly) specified the positive sense of rotation. The angular acceleration of magnitude 0.25 rad/s\(^2\) in the negative direction is assumed to be constant over a large time interval, including negative values (for \( t \)).
(a) We specify $\theta_{\text{max}}$ with the condition $\omega = 0$ (this is when the wheel reverses from positive rotation to rotation in the negative direction). We obtain $\theta_{\text{max}}$ using Eq. 10-14:

$$\theta_{\text{max}} = -\frac{\omega_0^2}{2\alpha} = -\frac{(4.7 \text{ rad/s})^2}{2(-0.25 \text{ rad/s}^2)} = 44 \text{ rad.}$$

(b) We find values for $t_1$ when the angular displacement (relative to its orientation at $t = 0$) is $\theta_1 = 22$ rad (or $22.09$ rad if we wish to keep track of accurate values in all intermediate steps and only round off on the final answers). Using Eq. 10-13 and the quadratic formula, we have

$$\theta_1 = \omega_0 t_1 + \frac{1}{2} \alpha t_1^2 \Rightarrow t_1 = \frac{-\omega_0 \pm \sqrt{\omega_0^2 + 2\alpha \theta_1}}{\alpha}$$

which yields the two roots $5.5$ s and $32$ s. Thus, the first time the reference line will be at $\theta_1 = 22$ rad is $t = 5.5$ s.

(c) The second time the reference line will be at $\theta_1 = 22$ rad is $t = 32$ s.

(d) We find values for $t_2$ when the angular displacement (relative to its orientation at $t = 0$) is $\theta_2 = -10.5$ rad. Using Eq. 10-13 and the quadratic formula, we have

$$\theta_2 = \omega_0 t_2 + \frac{1}{2} \alpha t_2^2 \Rightarrow t_2 = \frac{-\omega_0 \pm \sqrt{\omega_0^2 + 2\alpha \theta_2}}{\alpha}$$

which yields the two roots $-2.1$ s and $40$ s. Thus, at $t = -2.1$ s the reference line will be at $\theta_2 = -10.5$ rad.

(e) At $t = 40$ s the reference line will be at $\theta_2 = -10.5$ rad.

(f) With radians and seconds understood, the graph of $\theta$ versus $t$ is shown below (with the points found in the previous parts indicated as small dots).
18. (a) A complete revolution is an angular displacement of $\Delta \theta = 2\pi$ rad, so the angular velocity in rad/s is given by $\omega = \Delta \theta / T = 2\pi / T$. The angular acceleration is given by

$$\alpha = \frac{d\omega}{dt} = -\frac{2\pi}{T^2} \frac{dT}{dt}.$$ 

For the pulsar described in the problem, we have

$$\frac{dT}{dt} = \frac{1.26 \times 10^{-5}}{3.16 \times 10^7} \text{ s/y} = 4.00 \times 10^{-13}.$$ 

Therefore,

$$\alpha = \left(\frac{2\pi}{(0.033 \text{ s})^2}\right) (4.00 \times 10^{-13}) = -2.3 \times 10^{-9} \text{ rad/s}^2.$$ 

The negative sign indicates that the angular acceleration is opposite the angular velocity and the pulsar is slowing down.

(b) We solve $\omega = \omega_0 + \alpha t$ for the time $t$ when $\omega = 0$:

$$t = -\frac{\omega_0}{\alpha} = -\frac{2\pi}{\alpha T} = -\frac{2\pi}{(-2.3 \times 10^{-9} \text{ rad/s}^2)(0.033 \text{ s})} = 8.3 \times 10^{10} \text{ s} \approx 2.6 \times 10^3 \text{ years}$$

(c) The pulsar was born 1992–1054 = 938 years ago. This is equivalent to $(938 \text{ y})(3.16 \times 10^7 \text{ s/y}) = 2.96 \times 10^{10} \text{ s}$. Its angular velocity at that time was

$$\omega = \omega_0 + \alpha t + \frac{2\pi}{T} + \alpha t = \frac{2\pi}{0.033 \text{ s}} + (-2.3 \times 10^{-9} \text{ rad/s}^2)(-2.96 \times 10^{10} \text{ s}) = 258 \text{ rad/s}.$$ 

Its period was

$$T = \frac{2\pi}{\omega} = \frac{2\pi}{258 \text{ rad/s}} = 2.4 \times 10^{-2} \text{ s}.$$ 

19. (a) Converting from hours to seconds, we find the angular velocity (assuming it is positive) from Eq. 10-18:

$$\omega = \frac{v}{r} = \frac{(2.90 \times 10^4 \text{ km/h})(1.000 \text{ h} / 3600 \text{ s})}{3.22 \times 10^3 \text{ km}} = 2.50 \times 10^{-3} \text{ rad/s}.$$ 

(b) The radial (or centripetal) acceleration is computed according to Eq. 10-23:

$$a_r = \omega^2 r = (2.50 \times 10^{-3} \text{ rad/s})^2 (3.22 \times 10^6 \text{ m}) = 20.2 \text{ m/s}^2.$$
(c) Assuming the angular velocity is constant, then the angular acceleration and the tangential acceleration vanish, since

\[ \alpha = \frac{d\omega}{dt} = 0 \quad \text{and} \quad a_r = r\alpha = 0. \]

20. The function \( \theta = \xi e^{\beta t} \) where \( \xi = 0.40 \text{ rad} \) and \( \beta = 2 \text{ s}^{-1} \) is describing the angular coordinate of a line (which is marked in such a way that all points on it have the same value of angle at a given time) on the object. Taking derivatives with respect to time leads to \( \frac{d\theta}{dt} = \xi \beta e^{\beta t} \) and \( \frac{d^2\theta}{dt^2} = \xi \beta^2 e^{\beta t} \).

(a) Using Eq. 10-22, we have \( a_r = \alpha r = \frac{d^2\theta}{dt^2} r = 64 \text{ cm/s}^2 \).

(b) Using Eq. 10-23, we get \( a_r = \omega^2 r = \left(\frac{d\theta}{dt}\right)^2 r = 26 \text{ cm/s}^2 \).

21. We assume the given rate of \( 1.2 \times 10^{-3} \text{ m/y} \) is the linear speed of the top; it is also possible to interpret it as just the horizontal component of the linear speed but the difference between these interpretations is arguably negligible. Thus, Eq. 10-18 leads to

\[ \omega = \frac{1.2 \times 10^{-3} \text{ m/y}}{55 \text{ m}} = 2.18 \times 10^{-5} \text{ rad/y} \]

which we convert (since there are about \( 3.16 \times 10^7 \text{ s} \) in a year) to \( \omega = 6.9 \times 10^{-13} \text{ rad/s} \).

22. (a) Using Eq. 10-6, the angular velocity at \( t = 5.0 \text{ s} \) is

\[ \omega = \frac{d\theta}{dt} \bigg|_{t=5.0} = \frac{d}{dt} \left(0.30t^2\right) \bigg|_{t=5.0} = 2(0.30)(5.0) = 3.0 \text{ rad/s}. \]

(b) Equation 10-18 gives the linear speed at \( t = 5.0 \text{ s} \): \( v = \omega r = (3.0 \text{ rad/s})(10 \text{ m}) = 30 \text{ m/s} \).

(c) The angular acceleration is, from Eq. 10-8,

\[ \alpha = \frac{d\omega}{dt} = \frac{d}{dt} (0.60t) = 0.60 \text{ rad/s}^2. \]

Then, the tangential acceleration at \( t = 5.0 \text{ s} \) is, using Eq. 10-22,

\[ a_r = r\alpha = (10 \text{ m}) \left(0.60 \text{ rad/s}^2\right) = 6.0 \text{ m/s}^2. \]
(d) The radial (centripetal) acceleration is given by Eq. 10-23:

\[ a_r = \omega^2 r = (3.0 \text{ rad/s})^2 (10 \text{ m}) = 90 \text{ m/s}^2. \]

23. **THINK** A positive angular acceleration is required in order to increase the angular speed of the flywheel.

**EXPRESS** The linear speed of the flywheel is related to its angular speed by \( v = \omega r \), where \( r \) is the radius of the wheel. As the wheel is accelerated, its angular speed at a later time is \( \omega = \omega_0 + \alpha t \).

**ANALYZE** (a) The angular speed of the wheel, expressed in rad/s, is

\[ \omega_0 = \frac{(200 \text{ rev/min})(2\pi \text{ rad/rev})}{60 \text{ s/min}} = 20.9 \text{ rad/s}. \]

(b) With \( r = (1.20 \text{ m})/2 = 0.60 \text{ m} \), using Eq. 10-18, we find the linear speed to be

\[ v = r\omega_0 = (0.60 \text{ m})(20.9 \text{ rad/s}) = 12.5 \text{ m/s}. \]

(c) With \( t = 1 \text{ min} \), \( \omega = 1000 \text{ rev/min} \) and \( \omega_0 = 200 \text{ rev/min} \), Eq. 10-12 gives the required acceleration:

\[ \alpha = \frac{\omega - \omega_0}{t} = 800 \text{ rev/min}^2. \]

(d) With the same values used in part (c), Eq. 10-15 becomes

\[ \theta = \frac{1}{2} (\omega_0 + \omega) t = \frac{1}{2} (200 \text{ rev/min} + 1000 \text{ rev/min})(1.0 \text{ min}) = 600 \text{ rev}. \]

**LEARN** An alternative way to solve for (d) is to use Eq. 10-13:

\[ \theta = \theta_0 + \omega_0 t + \frac{1}{2} \alpha t^2 = 0 + (200 \text{ rev/min})(1.0 \text{ min}) + \frac{1}{2} (800 \text{ rev/min}^2)(1.0 \text{ min})^2 = 600 \text{ rev}. \]

24. Converting \( 33\frac{1}{3} \text{ rev/min} \) to radians-per-second, we get \( \omega = 3.49 \text{ rad/s} \). Combining \( v = \omega r \) (Eq. 10-18) with \( \Delta t = d/v \) where \( \Delta t \) is the time between bumps (a distance \( d \) apart), we arrive at the rate of striking bumps:

\[ \frac{1}{\Delta t} = \frac{\omega r}{d} \approx 199 \text{ /s}. \]

25. **THINK** The linear speed of a point on Earth’s surface depends on its distance from the Earth’s axis of rotation.
EXPRESS To solve for the linear speed, we use $v = \omega r$, where $r$ is the radius of its orbit. A point on Earth at a latitude of $40^\circ$ moves along a circular path of radius $r = R \cos 40^\circ$, where $R$ is the radius of Earth ($6.4 \times 10^6$ m). On the other hand, $r = R$ at the equator.

ANALYZE (a) Earth makes one rotation per day and $1 \text{ day} = (24 \text{ h})(3600 \text{ s/h}) = 8.64 \times 10^4 \text{ s}$, so the angular speed of Earth is

$$\omega = \frac{2\pi \text{ rad}}{8.64 \times 10^4 \text{ s}} = 7.3 \times 10^{-5} \text{ rad/s}.$$  

(b) At latitude of $40^\circ$, the linear speed is

$$v = \omega(R \cos 40^\circ) = (7.3 \times 10^{-5} \text{ rad/s})(6.4 \times 10^6 \text{ m})\cos 40^\circ = 3.5 \times 10^2 \text{ m/s}.$$  

(c) At the equator (and all other points on Earth) the value of $\omega$ is the same ($7.3 \times 10^{-5}$ rad/s).

(d) The latitude at the equator is $0^\circ$ and the speed is

$$v = \omega R = (7.3 \times 10^{-5} \text{ rad/s})(6.4 \times 10^6 \text{ m}) = 4.6 \times 10^2 \text{ m/s}.$$  

LEARN The linear speed at the poles is zero since $r = R \cos 90^\circ = 0$.

26. (a) The angular acceleration is

$$\alpha = \frac{\Delta \omega}{\Delta t} = \frac{0 - 150 \text{ rev/ min}}{(2.2 \text{ h})(60 \text{ min/ 1h})} = -1.14 \text{ rev/ min}^2.$$  

(b) Using Eq. 10-13 with $t = (2.2)(60) = 132 \text{ min}$, the number of revolutions is

$$\theta = \omega t + \frac{1}{2} \alpha t^2 = (150 \text{ rev/min})(132 \text{ min}) + \frac{1}{2}(-1.14 \text{ rev/min}^2)(132 \text{ min})^2 = 9.9 \times 10^3 \text{ rev}.$$  

(c) With $r = 500 \text{ mm}$, the tangential acceleration is

$$a_r = \alpha r = (-1.14 \text{ rev/ min}^2) \left( \frac{2\pi \text{ rad}}{1 \text{ rev}} \right) \left( \frac{1 \text{ min}}{60 \text{ s}} \right)^2 (500 \text{ mm})$$

which yields $a_r = -0.99 \text{ mm/s}^2$.

(d) The angular speed of the flywheel is

$$\omega = (75 \text{ rev/min})(2\pi \text{ rad/rev})(1 \text{ min/ 60 s}) = 7.85 \text{ rad/s}.$$
With \( r = 0.50 \text{ m} \), the radial (or centripetal) acceleration is given by Eq. 10-23:

\[
a_r = \omega^2 r = (7.85 \text{ rad/s})^2 (0.50 \text{ m}) \approx 31 \text{ m/s}^2
\]

which is much bigger than \( a_t \). Consequently, the magnitude of the acceleration is

\[
|\vec{a}| = \sqrt{a_r^2 + a_t^2} \approx a_r = 31 \text{ m/s}^2.
\]

27. (a) The angular speed in rad/s is

\[
\omega = \left( 33.1 \frac{\text{rev}}{\text{min}} \right) \left( \frac{2\pi \text{ rad}}{\text{rev}} \right) \left( \frac{60 \text{ s}}{\text{min}} \right) = 3.49 \text{ rad/s}.
\]

Consequently, the radial (centripetal) acceleration is (using Eq. 10-23)

\[
a = \omega^2 r = (3.49 \text{ rad/s})^2 (6.0 \times 10^{-2} \text{ m}) = 0.73 \text{ m/s}^2.
\]

(b) Using Ch. 6 methods, we have \( ma = f_t \leq f_{s,\text{max}} = \mu_s mg \), which is used to obtain the (minimum allowable) coefficient of friction:

\[
\mu_{s, \text{min}} = \frac{a}{g} = \frac{0.73}{9.8} = 0.075.
\]

(c) The radial acceleration of the object is \( a_r = \omega^2 r \), while the tangential acceleration is \( a_t = \alpha r \). Thus,

\[
|\vec{a}| = \sqrt{a_r^2 + a_t^2} = \sqrt{\omega^4 r^2 + (\alpha r)^2} = r \sqrt{\omega^4 + \alpha^2}.
\]

If the object is not to slip at any time, we require

\[
f_{s, \text{max}} = \mu_s mg = ma_{\text{max}} = mr \sqrt{\omega_{\text{max}}^4 + \alpha^2}.
\]

Thus, since \( \alpha = \omega \alpha t \) (from Eq. 10-12), we find

\[
\mu_{s, \text{min}} = \frac{r \sqrt{\omega_{\text{max}}^4 + \alpha^2}}{g} = \frac{r \sqrt{\omega_{\text{max}}^4 + (\omega_{\text{max}} \alpha t)^2}}{g} = \frac{(0.060) \sqrt{3.49^4 + (3.4/0.25)^2}}{9.8} = 0.11.
\]

28. Since the belt does not slip, a point on the rim of wheel \( C \) has the same tangential acceleration as a point on the rim of wheel \( A \). This means that \( \alpha_A r_A = \alpha_C r_C \), where \( \alpha_A \) is the angular acceleration of wheel \( A \) and \( \alpha_C \) is the angular acceleration of wheel \( C \). Thus,
\[ \alpha_c = \left( \frac{r_h}{r_c} \right) \alpha_c = \left( \frac{10 \text{ cm}}{25 \text{ cm}} \right) (1.6 \text{ rad} / \text{s}^2) = 0.64 \text{ rad} / \text{s}^2. \]

With the angular speed of wheel \( C \) given by \( \omega_C = \alpha_C t \), the time for it to reach an angular speed of \( \omega = 100 \text{ rev/min} = 10.5 \text{ rad/s} \) starting from rest is

\[ t = \frac{\omega_C}{\alpha_c} = \frac{10.5 \text{ rad} / \text{s}}{0.64 \text{ rad} / \text{s}^2} = 16 \text{ s}. \]

29. (a) In the time light takes to go from the wheel to the mirror and back again, the wheel turns through an angle of \( \theta = 2\pi/500 = 1.26 \times 10^{-2} \text{ rad} \). That time is

\[ t = \frac{2\ell}{c} = \frac{2(500 \text{ m})}{2.998 \times 10^8 \text{ m/s}} = 3.34 \times 10^{-6} \text{ s} \]

so the angular velocity of the wheel is

\[ \omega = \frac{\theta}{t} = \frac{1.26 \times 10^{-2} \text{ rad}}{3.34 \times 10^{-6} \text{ s}} = 3.8 \times 10^3 \text{ rad/s}. \]

(b) If \( r \) is the radius of the wheel, the linear speed of a point on its rim is

\[ v = \omega r = (3.8 \times 10^3 \text{ rad/s} \cdot 0.050 \text{ m}) = 1.9 \times 10^3 \text{ m/s}. \]

30. (a) The tangential acceleration, using Eq. 10-22, is

\[ a_t = \alpha r = (14.2 \text{ rad} / \text{s}^2 \cdot 2.83 \text{ cm}) = 40.2 \text{ cm/s}^2. \]

(b) In rad/s, the angular velocity is \( \omega = (2760)(2\pi/60) = 289 \text{ rad/s} \), so

\[ a_t = \omega^2 r = (289 \text{ rad/s})^2 (0.0283 \text{ m}) = 2.36 \times 10^3 \text{ m/s}^2. \]

(c) The angular displacement is, using Eq. 10-14,

\[ \theta = \frac{\omega^2}{2\alpha} = \frac{(289 \text{ rad/s})^2}{2(14.2 \text{ rad/s}^2)} = 2.94 \times 10^3 \text{ rad}. \]

Then, using Eq. 10-1, the distance traveled is

\[ s = r\theta = (0.0283 \text{ m})(2.94 \times 10^3 \text{ rad}) = 83.2 \text{ m}. \]
31. (a) The upper limit for centripetal acceleration (same as the radial acceleration—see Eq. 10-23) places an upper limit of the rate of spin (the angular velocity \( \omega \)) by considering a point at the rim \((r = 0.25 \text{ m})\). Thus, \( \omega_{\text{max}} = \sqrt{a/r} = 40 \text{ rad/s}\). Now we apply Eq. 10-15 to first half of the motion (where \( \omega_0 = 0 \)):

\[
\theta - \theta_0 = \frac{1}{2}(\omega_0 + \omega)t \implies 400 \text{ rad} = \frac{1}{2}(0 + 40 \text{ rad/s})t
\]

which leads to \( t = 20 \text{ s} \). The second half of the motion takes the same amount of time (the process is essentially the reverse of the first); the total time is therefore 40 s.

(b) Considering the first half of the motion again, Eq. 10-11 leads to

\[
\omega = \omega_0 + \alpha t \implies \alpha = \frac{40 \text{ rad/s}}{20 \text{ s}} = 2.0 \text{ rad/s}^2.
\]

32. (a) The linear speed at \( t = 15.0 \text{ s} \) is

\[
v = a_r t = (0.500 \text{ m/s}^2) (15.0 \text{ s}) = 7.50 \text{ m/s}.
\]

The radial (centripetal) acceleration at that moment is

\[
a_r = \frac{v^2}{r} = \frac{(7.50 \text{ m/s})^2}{30.0 \text{ m}} = 1.875 \text{ m/s}^2.
\]

Thus, the net acceleration has magnitude:

\[
a = \sqrt{a_r^2 + a_r^2} = \sqrt{(0.500 \text{ m/s}^2)^2 + (1.875 \text{ m/s}^2)^2} = 1.94 \text{ m/s}^2.
\]

(b) We note that \( \vec{a}_i \parallel \vec{v} \). Therefore, the angle between \( \vec{v} \) and \( \vec{a} \) is

\[
\tan^{-1} \left( \frac{a_r}{a_r} \right) = \tan^{-1} \left( \frac{1.875}{0.5} \right) = 75.1^\circ
\]

so that the vector is pointing more toward the center of the track than in the direction of motion.

33. **THINK** We want to calculate the rotational inertia of a wheel, given its rotational energy and rotational speed.

**EXPRESS** The kinetic energy (in J) is given by \( K = \frac{1}{2} I \omega^2 \), where \( I \) is the rotational inertia (in kg \cdot m^2) and \( \omega \) is the angular velocity (in rad/s).
ANALYZE Expressing the angular speed as

$$\omega = \frac{(602 \text{ rev/min})(2\pi \text{ rad/rev})}{60 \text{ s/min}} = 63.0 \text{ rad/s},$$

we find the rotational inertia to be

$$I = \frac{2K}{\omega^2} = \frac{2(24400 \text{ J})}{(63.0 \text{ rad/s})^2} = 12.3 \text{ kg} \cdot \text{m}^2.$$

LEARN Note the analogy between rotational kinetic energy \(\frac{1}{2}I\omega^2\) and \(\frac{1}{2}mv^2\), the kinetic energy associated with linear motion.

34. (a) Equation 10-12 implies that the angular acceleration \(\alpha\) should be the slope of the \(\omega\) vs \(t\) graph. Thus, \(\alpha = 9/6 = 1.5 \text{ rad/s}^2\).

(b) By Eq. 10-34, \(K\) is proportional to \(\omega^2\). Since the angular velocity at \(t = 0\) is \(-2 \text{ rad/s}\) (and this value squared is 4) and the angular velocity at \(t = 4 \text{ s}\) is \(4 \text{ rad/s}\) (and this value squared is 16), then the ratio of the corresponding kinetic energies must be

$$\frac{K_0}{K_1} = \frac{4}{16} \Rightarrow K_0 = K_1/4 = 0.40 \text{ J}.$$

35. THINK The rotational inertia of a rigid body depends on how its mass is distributed.

EXPRESS Since the rotational inertia of a cylinder is \(I = \frac{1}{2} MR^2\) (Table 10-2(c)), its rotational kinetic energy is

$$K = \frac{1}{2} I\omega^2 = \frac{1}{4} MR^2 \omega^2.$$  

ANALYZE (a) For the smaller cylinder, we have

$$K_1 = \frac{1}{4} (1.25 \text{ kg})(0.25 \text{ m})^2(235 \text{ rad/s})^2 = 1.08 \times 10^3 \text{ J}.$$  

(b) For the larger cylinder, we obtain

$$K_2 = \frac{1}{4} (1.25 \text{ kg})(0.75 \text{ m})^2(235 \text{ rad/s})^2 = 9.71 \times 10^3 \text{ J}.$$  

LEARN The ratio of the rotational kinetic energies of the two cylinders having the same mass and angular speed is

$$\frac{K_2}{K_1} = \left(\frac{R_2}{R_1}\right)^2 = \left(\frac{0.75 \text{ m}}{0.25 \text{ m}}\right)^2 = 9.$$
36. The parallel axis theorem (Eq. 10-36) shows that \( I \) increases with \( h \). The phrase “out to the edge of the disk” (in the problem statement) implies that the maximum \( h \) in the graph is, in fact, the radius \( R \) of the disk. Thus, \( R = 0.20 \) m. Now we can examine, say, the \( h = 0 \) datum and use the formula for \( I_{\text{com}} \) (see Table 10-2(c)) for a solid disk, or (which might be a little better, since this is independent of whether it is really a solid disk) we can compare the difference between the \( h = 0 \) datum and the \( h = h_{\text{max}} = R \) datum and relate that difference to the parallel axis theorem (thus the difference is \( M(h_{\text{max}})^2 = 0.10 \) kg \( \cdot \) m\(^2\)). In either case, we arrive at \( M = 2.5 \) kg.

37. THINK We want to calculate the rotational inertia of a meter stick about an axis perpendicular to the stick but not through its center.

EXPRESSION We use the parallel-axis theorem: \( I = I_{\text{com}} + Mh^2 \), where \( I_{\text{com}} \) is the rotational inertia about the center of mass (see Table 10-2(d)), \( M \) is the mass, and \( h \) is the distance between the center of mass and the chosen rotation axis. The center of mass is at the center of the meter stick, which implies \( h = 0.50 \) m \(-\) 0.20 m = 0.30 m.

ANALYZE With \( M = 0.56 \) kg and \( L = 1.0 \) m, we have

\[
I_{\text{com}} = \frac{1}{12} ML^2 = \frac{1}{12} (0.56 \text{ kg})(1.0 \text{ m})^2 = 4.67 \times 10^{-2} \text{ kg} \cdot \text{m}^2.
\]

Consequently, the parallel-axis theorem yields

\[
I = 4.67 \times 10^{-2} \text{ kg} \cdot \text{m}^2 + (0.56 \text{ kg})(0.30 \text{ m})^2 = 9.7 \times 10^{-2} \text{ kg} \cdot \text{m}^2.
\]

LEARN A greater moment of inertia \( I > I_{\text{com}} \) means that it is more difficult to rotate the meter stick about this axis than the case where the axis passes through the center.

38. (a) Equation 10-33 gives

\[
I_{\text{total}} = md^2 + m(2d)^2 + m(3d)^2 = 14 \text{ md}^2.
\]

If the innermost one is removed then we would only obtain \( m(2d)^2 + m(3d)^2 = 13 \text{ md}^2 \). The percentage difference between these is \( (13 - 14)/14 = 0.0714 \approx 7.1\% \).

(b) If, instead, the outermost particle is removed, we would have \( md^2 + m(2d)^2 = 5 \text{ md}^2 \). The percentage difference in this case is \( 0.643 \approx 64\% \).

39. (a) Using Table 10-2(c) and Eq. 10-34, the rotational kinetic energy is

\[
K = \frac{1}{2} I \omega^2 = \frac{1}{2} \left( \frac{1}{2} MR^2 \right) \omega^2 = \frac{1}{4} (500 \text{ kg})(200 \pi \text{ rad/s})(1.0 \text{ m})^2 = 4.9 \times 10^7 \text{ J}.
\]

(b) We solve \( P = K/t \) (where \( P \) is the average power) for the operating time \( t \).
\[ I = \frac{K}{P} = \frac{4.9 \times 10^7 \text{J}}{8.0 \times 10^7 \text{W}} = 6.2 \times 10^{-3} \text{ s} \]

which we rewrite as \( t \approx 1.0 \times 10^2 \text{ min.} \)

40. (a) Consider three of the disks (starting with the one at point \( O \)): \( \oplus \)OO . The first one (the one at point \( O \), shown here with the plus sign inside) has rotational inertial (see item (c) in Table 10-2) \( I = \frac{1}{2} mR^2 \). The next one (using the parallel-axis theorem) has

\[ I = \frac{1}{2} mR^2 + mh^2 \]

where \( h = 2R \). The third one has \( I = \frac{1}{2} mR^2 + m(4R)^2 \). If we had considered five of the disks \( \text{OO} \oplus \text{OO} \) with the one at \( O \) in the middle, then the total rotational inertia is

\[ I = 5\left(\frac{1}{2} mR^2\right) + 2(m(2R)^2 + m(4R)^2). \]

The pattern is now clear and we can write down the total \( I \) for the collection of fifteen disks:

\[ I = 15\left(\frac{1}{2} mR^2\right) + 2(m(2R)^2 + m(4R)^2 + m(6R)^2 + \ldots + m(14R)^2) = \frac{2255}{2} mR^2. \]

The generalization to \( N \) disks (where \( N \) is assumed to be an odd number) is

\[ I = \frac{1}{6}(2N^2 + 1)NmR^2. \]

In terms of the total mass (\( m = M/15 \)) and the total length (\( R = L/30 \)), we obtain

\[ I = 0.083519ML^2 \approx (0.08352)(0.1000 \text{ kg})(1.0000 \text{ m})^2 = 8.352 \times 10^{-3} \text{ kg} \cdot \text{m}^2. \]

(b) Comparing to the formula \((e)\) in Table 10-2 (which gives roughly \( I = 0.08333 ML^2 \)), we find our answer to part (a) is 0.22% lower.

41. The particles are treated “point-like” in the sense that Eq. 10-33 yields their rotational inertia, and the rotational inertia for the rods is figured using Table 10-2(e) and the parallel-axis theorem (Eq. 10-36).

(a) With subscript 1 standing for the rod nearest the axis and 4 for the particle farthest from it, we have
495

\[ I = I_1 + I_2 + I_3 + I_4 = \left( \frac{1}{12}Md^2 + M\left( \frac{1}{2}d \right)^2 \right) + md^2 + \left( \frac{1}{12}Md^2 + M\left( \frac{3}{2}d \right)^2 \right) + m(2d)^2 \]

\[ = \frac{8}{3}Md^2 + 5md^2 = \frac{8}{3}(1.2 \text{ kg})(0.056 \text{ m})^2 + 5(0.85 \text{ kg})(0.056 \text{ m})^2 \]

\[ = 0.023 \text{ kg} \cdot \text{m}^2. \]

(b) Using Eq. 10-34, we have

\[ K = \frac{1}{2}I\omega^2 = \left( \frac{4}{3}M + \frac{5}{2}m \right) d^2\omega^2 = \left[ \frac{4}{3}(1.2 \text{ kg}) + \frac{5}{2}(0.85 \text{ kg}) \right] (0.056 \text{ m})^2(0.30 \text{ rad/s})^2 \]

\[ = 1.1 \times 10^{-3} \text{ J}. \]

42. (a) We apply Eq. 10-33:

\[ I_x = \sum_{i=1}^{4} m_i y_i^2 = \left[ 50(2.0)^2 + (25)(4.0)^2 + 25(-3.0)^2 + 30(4.0)^2 \right] \text{g} \cdot \text{cm}^2 = 1.3 \times 10^3 \text{ g} \cdot \text{cm}^2. \]

(b) For rotation about the y axis we obtain

\[ I_y = \sum_{i=1}^{4} m_i x_i^2 = 50(2.0)^2 + (25)(0)^2 + 25(3.0)^2 + 30(2.0)^2 = 5.5 \times 10^2 \text{ g} \cdot \text{cm}^2. \]

(c) And about the z axis, we find (using the fact that the distance from the z axis is \( \sqrt{x^2 + y^2} \))

\[ I_z = \sum_{i=1}^{4} m_i (x_i^2 + y_i^2) = I_x + I_y = 1.3 \times 10^3 + 5.5 \times 10^2 = 1.9 \times 10^2 \text{ g} \cdot \text{cm}^2. \]

(d) Clearly, the answer to part (c) is \( A + B \).

43. THINK Since the rotation axis does not pass through the center of the block, we use the parallel-axis theorem to calculate the rotational inertia.

EXPRESS According to Table 10-2(i), the rotational inertia of a uniform slab about an axis through the center and perpendicular to the large faces is given by

\[ I_{\text{com}} = \frac{M}{12} (a^2 + b^2). \]

A parallel axis through the corner is a distance \( h = \sqrt{(a/2)^2 + (b/2)^2} \) from the center. Therefore,

\[ I = I_{\text{com}} + Mh^2 = \frac{M}{12} (a^2 + b^2) + \frac{M}{4} (a^2 + b^2) = \frac{M}{3} (a^2 + b^2). \]

ANALYZE With \( M = 0.172 \text{ kg}, a = 3.5 \text{ cm} \) and \( b = 8.4 \text{ cm} \), we have
LEARN A greater moment of inertia \( I > I_{\text{com}} \) means that it is more difficult to rotate the block about the axis through the corner than the case where the axis passes through the center.

44. (a) We show the figure with its axis of rotation (the thin horizontal line).

We note that each mass is \( r = 1.0 \) m from the axis. Therefore, using Eq. 10-26, we obtain

\[
I = \sum m_i r_i^2 = 4 (0.50 \text{ kg}) (1.0 \text{ m})^2 = 2.0 \text{ kg} \cdot \text{m}^2 .
\]

(b) In this case, the two masses nearest the axis are \( r = 1.0 \) m away from it, but the two furthest from the axis are \( r = \sqrt{(1.0 \text{ m})^2 + (2.0 \text{ m})^2} \) from it. Here, then, Eq. 10-33 leads to

\[
I = \sum m_i r_i^2 = 2(0.50 \text{ kg}) (1.0 \text{ m}^2) + 2(0.50 \text{ kg}) (5.0 \text{ m}^2) = 6.0 \text{ kg} \cdot \text{m}^2 .
\]

(c) Now, two masses are on the axis (with \( r = 0 \)) and the other two are a distance \( r = \sqrt{(1.0 \text{ m})^2 + (1.0 \text{ m})^2} \) away. Now we obtain \( I = 2.0 \text{ kg} \cdot \text{m}^2 .\)

45. THINK Torque is the product of the force applied and the moment arm. When two torques act on a body, the net torque is their vector sum.

EXPRESS We take a torque that tends to cause a counterclockwise rotation from rest to be positive and a torque tending to cause a clockwise rotation to be negative. Thus, a positive torque of magnitude \( r_1 F_1 \sin \theta_1 \) is associated with \( \vec{F}_1 \) and a negative torque of magnitude \( r_2 F_2 \sin \theta_2 \) is associated with \( \vec{F}_2 \). The net torque is consequently

\[
\tau = r_1 F_1 \sin \theta_1 - r_2 F_2 \sin \theta_2 .
\]

ANALYZE Substituting the given values, we obtain

\[
\tau = r_1 F_1 \sin \theta_1 - r_2 F_2 \sin \theta_2 = (1.30 \text{ m})(4.20 \text{ N}) \sin 75^\circ - (2.15 \text{ m})(4.90 \text{ N}) \sin 60^\circ \\
= -3.85 \text{ N} \cdot \text{m} .
\]
LEARN Since $\tau < 0$, the body will rotate clockwise about the pivot point.

46. The net torque is

$$\tau = \tau_A + \tau_B + \tau_C = F_A r_A \sin \phi_A - F_B r_B \sin \phi_B + F_C r_C \sin \phi_C$$

$$= (10)(8.0) \sin 135^\circ - (16)(4.0) \sin 90^\circ + (19)(3.0) \sin 160^\circ$$

$$= 12 \text{ N} \cdot \text{m}.$$

47. THINK In this problem we have a pendulum made up of a ball attached to a massless rod. There are two forces acting on the ball, the force of the rod and the force of gravity.

EXPRESS No torque about the pivot point is associated with the force of the rod since that force is along the line from the pivot point to the ball. As can be seen from the diagram, the component of the force of gravity that is perpendicular to the rod is $mg \sin \theta$. If $\ell$ is the length of the rod, then the torque associated with this force has magnitude

$$\tau = mg \ell \sin \theta.$$

ANALYZE With $m = 0.75 \text{ kg}$, $\ell = 1.25 \text{ m}$ and $\theta = 30^\circ$, we find the torque to be

$$\tau = mg \ell \sin \theta = (0.75)(9.8)(1.25) \sin 30^\circ = 4.6 \text{ N} \cdot \text{m}.$$

LEARN The moment arm of the gravitational force $mg$ is $\ell \sin \theta$. Alternatively, we may say that $\ell$ is the moment arm of $mg \sin \theta$, the tangential component of the gravitational force. Both interpretations lead to the same result: $\tau = (mg)(\ell \sin \theta) = (mg \sin \theta)(\ell)$.

48. We compute the torques using $\tau = rF \sin \phi$.

(a) For $\phi = 30^\circ$, $\tau_a = (0.152 \text{ m})(111 \text{ N}) \sin 30^\circ = 8.4 \text{ N} \cdot \text{m}$.

(b) For $\phi = 90^\circ$, $\tau_b = (0.152 \text{ m})(111 \text{ N}) \sin 90^\circ = 17 \text{ N} \cdot \text{m}$.

(c) For $\phi = 180^\circ$, $\tau_c = (0.152 \text{ m})(111 \text{ N}) \sin 180^\circ = 0$.

49. THINK Since the angular velocity of the diver changes with time, there must be a non-vanishing angular acceleration.
**EXPRESS** To calculate the angular acceleration \( \alpha \), we use the kinematic equation 
\[
\omega = \omega_0 + \alpha t,
\]
where \( \omega_0 \) is the initial angular velocity, \( \omega \) is the final angular velocity and \( t \) is the time. If \( I \) is the rotational inertia of the diver, then the magnitude of the torque acting on her is \( \tau = I\alpha \).

**ANALYZE** (a) Using the values given, the angular acceleration is
\[
\alpha = \frac{\omega - \omega_0}{t} = \frac{6.20 \text{ rad/s}}{220 \times 10^{-3} \text{ s}} = 28.2 \text{ rad/s}^2.
\]
(b) Similarly, we find the magnitude of the torque on the diver to be
\[
\tau = I\alpha = (12.0 \text{ kg} \cdot \text{m}^2)(28.2 \text{ rad/s}^2) = 3.38 \times 10^2 \text{ N} \cdot \text{m}.
\]

**LEARN** A net torque results in an angular acceleration that changes angular velocity. The equation \( \tau = I\alpha \) implies that the greater the rotational inertia \( I \), the greater the torque required for a given angular acceleration \( \alpha \).

50. The rotational inertia is found from Eq. 10-45.
\[
I = \frac{\tau}{\alpha} = \frac{32.0}{25.0} = 1.28 \text{ kg} \cdot \text{m}^2
\]

51. (a) We use constant acceleration kinematics. If down is taken to be positive and \( a \) is the acceleration of the heavier block \( m_2 \), then its coordinate is given by 
\[
y = \frac{1}{2}at^2,
\]
so
\[
a = \frac{2y}{t^2} = \frac{2(0.750 \text{ m})}{(5.00 \text{ s})^2} = 6.00 \times 10^{-2} \text{ m/s}^2.
\]
Block 1 has an acceleration of \( 6.00 \times 10^{-2} \text{ m/s}^2 \) upward.

(b) Newton’s second law for block 2 is \( m_2g - T_2 = m_2a \), where \( m_2 \) is its mass and \( T_2 \) is the tension force on the block. Thus,
\[
T_2 = m_2(g - a) = (0.500 \text{ kg}) (9.8 \text{ m/s}^2 - 6.00 \times 10^{-2} \text{ m/s}^2) = 4.87 \text{ N}.
\]

(c) Newton’s second law for block 1 is \( m_1g - T_1 = -m_1a \), where \( T_1 \) is the tension force on the block. Thus,
\[
T_1 = m_1(g + a) = (0.460 \text{ kg}) (9.8 \text{ m/s}^2 + 6.00 \times 10^{-2} \text{ m/s}^2) = 4.54 \text{ N}.
\]
(d) Since the cord does not slip on the pulley, the tangential acceleration of a point on the rim of the pulley must be the same as the acceleration of the blocks, so
\[ \alpha = \frac{a}{R} = \frac{6.00 \times 10^{-2} \text{ m/s}^2}{5.00 \times 10^{-2} \text{ m}} = 1.20 \text{ rad/s}^2. \]

(e) The net torque acting on the pulley is \( \tau = (T_2 - T_1)R \). Equating this to \( I\alpha \) we solve for the rotational inertia:

\[ I = \frac{(T_2 - T_1)R}{\alpha} = \frac{(4.87 \text{ N} - 4.54 \text{ N})(5.00 \times 10^{-2} \text{ m})}{1.20 \text{ rad/s}^2} = 1.38 \times 10^{-2} \text{ kg} \cdot \text{m}^2. \]

52. According to the sign conventions used in the book, the magnitude of the net torque exerted on the cylinder of mass \( m \) and radius \( R \) is

\[ \tau_{\text{net}} = F_1R - F_2R - F_3r = (6.0 \text{ N})(0.12 \text{ m}) - (4.0 \text{ N})(0.12 \text{ m}) - (2.0 \text{ N})(0.050 \text{ m}) = 71 \text{ N} \cdot \text{m}. \]

(a) The resulting angular acceleration of the cylinder (with \( I = \frac{1}{2} MR^2 \) according to Table 10-2(c)) is

\[ \alpha = \frac{\tau_{\text{net}}}{I} = \frac{71 \text{ N} \cdot \text{m}}{\frac{1}{2}(2.0\text{ kg})(0.12 \text{ m})^2} = 9.7 \text{ rad/s}^2. \]

(b) The direction is counterclockwise (which is the positive sense of rotation).

53. Combining Eq. 10-45 (\( \tau_{\text{net}} = I\alpha \)) with Eq. 10-38 gives \( RF_2 - RF_1 = I\alpha \), where \( \alpha = \omega/t \) by Eq. 10-12 (with \( \omega_0 = 0 \)). Using item (c) in Table 10-2 and solving for \( F_2 \) we find

\[ F_2 = \frac{MR\omega}{2t} + F_1 = \frac{(0.02)(0.02)(250)}{2(1.25)} + 0.1 = 0.140 \text{ N}. \]

54. (a) In this case, the force is \( mg = (70 \text{ kg})(9.8 \text{ m/s}^2) \), and the “lever arm” (the perpendicular distance from point \( O \) to the line of action of the force) is 0.28 m. Thus, the torque (in absolute value) is \( (70 \text{ kg})(9.8 \text{ m/s}^2)(0.28 \text{ m}) \). Since the moment-of-inertia is \( I = 65 \text{ kg} \cdot \text{m}^2 \), then Eq. 10-45 gives \( |\alpha| = 2.955 \approx 3.0 \text{ rad/s}^2 \).

(b) Now we have another contribution \( (1.4 \text{ m} \times 300 \text{ N}) \) to the net torque, so

\[ |\tau_{\text{net}}| = (70 \text{ kg})(9.8 \text{ m/s}^2)(0.28 \text{ m}) + (1.4 \text{ m})(300 \text{ N}) = (65 \text{ kg} \cdot \text{m}^2) |\alpha| \]

which leads to \( |\alpha| = 9.4 \text{ rad/s}^2 \).

55. Combining Eq. 10-34 and Eq. 10-45, we have \( RF = I\alpha \), where \( \alpha \) is given by \( \omega/t \) (according to Eq. 10-12, since \( \omega_0 = 0 \) in this case). We also use the fact that
CHAPTER 10

\[ I = I_{\text{plate}} + I_{\text{disk}} \]

where \( I_{\text{disk}} = \frac{1}{2} MR^2 \) (item (c) in Table 10-2). Therefore,

\[ I_{\text{plate}} = \frac{RFt}{\omega} - \frac{1}{2} MR^2 = 2.51 \times 10^{-4} \text{ kg} \cdot \text{m}^2. \]

56. With counterclockwise positive, the angular acceleration \( \alpha \) for both masses satisfies

\[ \tau = mgL_1 - mgL_2 = I\alpha = (mL_1^2 + mL_2^2)\alpha, \]

by combining Eq. 10-45 with Eq. 10-39 and Eq. 10-33. Therefore, using SI units,

\[ \alpha = \frac{g(L_1 - L_2)}{L_1^2 + L_2^2} = \frac{(9.8 \text{ m/s}^2)(0.20 \text{ m} - 0.80 \text{ m})}{(0.20 \text{ m})^2 + (0.80 \text{ m})^2} = -8.65 \text{ rad/s}^2 \]

where the negative sign indicates the system starts turning in the clockwise sense. The magnitude of the acceleration vector involves no radial component (yet) since it is evaluated at \( t = 0 \) when the instantaneous velocity is zero. Thus, for the two masses, we apply Eq. 10-22:

(a) \(|\bar{a}_1| = |\alpha|L_1 = (8.65 \text{ rad/s}^2)(0.20 \text{ m}) = 1.7 \text{ m/s}.

(b) \(|\bar{a}_2| = |\alpha|L_2 = (8.65 \text{ rad/s}^2)(0.80 \text{ m}) = 6.9 \text{ m/s}^2.

57. Since the force acts tangentially at \( r = 0.10 \text{ m} \), the angular acceleration (presumed positive) is

\[ \alpha = \frac{\tau}{I} = \frac{Fr}{I} = \frac{(0.5t + 0.3t^2)(0.10)}{1.0 \times 10^{-3}} = 50t + 30t^2 \]

in SI units (rad/s\(^2\)).

(a) At \( t = 3 \text{ s} \), the above expression becomes \( \alpha = 4.2 \times 10^2 \text{ rad/s}^2 \).

(b) We integrate the above expression, noting that \( \omega_0 = 0 \), to obtain the angular speed at \( t = 3 \text{ s} \):

\[ \omega = \int_0^3 \alpha \, dt = \left(25t^2 + 10t^3\right) \bigg|_0^3 = 5.0 \times 10^3 \text{ rad/s}. \]

58. (a) The speed of \( v \) of the mass \( m \) after it has descended \( d = 50 \text{ cm} \) is given by \( v^2 = 2ad \) (Eq. 2-16). Thus, using \( g = 980 \text{ cm/s}^2 \), we have
\[ v = \sqrt{2ad} = \sqrt{\frac{2(2mg)d}{M + 2m}} = \sqrt{\frac{4(50)(980)(50)}{400 + 2(50)}} = 1.4 \times 10^2 \text{ cm/s}. \]

(b) The answer is still \( 1.4 \times 10^2 \text{ cm/s} = 1.4 \text{ m/s}, \) since it is independent of \( R. \)

59. With \( \omega = (1800)(2\pi/60) = 188.5 \text{ rad/s}, \) we apply Eq. 10-55:

\[ P = \tau \omega \quad \Rightarrow \quad \tau = \frac{74600 \text{ W}}{188.5 \text{ rad/s}} = 396 \text{ N} \cdot \text{m}. \]

60. (a) We apply Eq. 10-34:

\[ K = \frac{1}{2} I \omega^2 = \frac{1}{2} \left( \frac{1}{3} mL^2 \right) \omega^2 = \frac{1}{6} mL^2 \omega^2 \]

\[ = \frac{1}{6} (0.42 \text{ kg})(0.75 \text{ m})^2(4.0 \text{ rad/s})^2 = 0.63 \text{ J}. \]

(b) Simple conservation of mechanical energy leads to \( K = mgh. \) Consequently, the center of mass rises by

\[ h = \frac{K}{mg} = \frac{mL^2 \omega^2}{6mg} = \frac{L^2 \omega^2}{6g} = \frac{(0.75 \text{ m})^2(4.0 \text{ rad/s})^2}{6(9.8 \text{ m/s}^2)} = 0.153 \text{ m} \approx 0.15 \text{ m}. \]

61. The initial angular speed is \( \omega = (280 \text{ rev/min})(2\pi/60) = 29.3 \text{ rad/s}. \)

(a) Since the rotational inertia is (Table 10-2(a)) \( I = (32 \text{ kg})(1.2 \text{ m})^2 = 46.1 \text{ kg} \cdot \text{m}^2, \) the work done is

\[ W = \Delta K = 0 - \frac{1}{2} I \omega^2 = -\frac{1}{2} (46.1 \text{ kg} \cdot \text{m}^2)(29.3 \text{ rad/s})^2 = -1.98 \times 10^4 \text{ J}. \]

(b) The average power (in absolute value) is therefore

\[ |P| = \frac{|W|}{\Delta t} = \frac{19.8 \times 10^3}{15} = 1.32 \times 10^3 \text{ W}. \]

62. (a) Eq. 10-33 gives

\[ I_{\text{total}} = md^2 + m(2d)^2 + m(3d)^2 = 14 \text{ md}^2, \]

where \( d = 0.020 \text{ m} \) and \( m = 0.010 \text{ kg}. \) The work done is

\[ W = \Delta K = \frac{1}{2} I \omega_f^2 - \frac{1}{2} I \omega_i^2, \]
where $\omega_f = 20 \text{ rad/s}$ and $\omega_i = 0$. This gives $W = 11.2 \text{ mJ}$.

(b) Now, $\omega_f = 40 \text{ rad/s}$ and $\omega_i = 20 \text{ rad/s}$, and we get $W = 33.6 \text{ mJ}$.

(c) In this case, $\omega_f = 60 \text{ rad/s}$ and $\omega_i = 40 \text{ rad/s}$. This gives $W = 56.0 \text{ mJ}$.

(d) Equation 10-34 indicates that the slope should be $\frac{1}{2}I$. Therefore, it should be

$$7md^2 = 2.80 \times 10^{-5} \text{ J/s}^2/\text{ rad}^2.$$ 

63. **THINK** As the meter stick falls by rotating about the axis passing through one end of the stick, its potential energy is converted into rotational kinetic energy.

**EXPRESS** We use $\ell$ to denote the length of the stick. The meter stick is initially at rest so its initial kinetic energy is zero. Since its center of mass is $\ell/2$ from either end, its initial potential energy is $U_g = \frac{1}{2}mg\ell$, where $m$ is its mass. Just before the stick hits the floor, its final potential energy is zero, and its final kinetic energy is $\frac{1}{2}I\omega^2$, where $I$ is its rotational inertia about an axis passing through one end of the stick and $\omega$ is the angular velocity. Conservation of energy yields

$$\frac{1}{2}mg\ell = \frac{1}{2}I\omega^2 \Rightarrow \omega = \sqrt{\frac{mg\ell}{I}}.$$ 

The free end of the stick is a distance $\ell$ from the rotation axis, so its speed as it hits the floor is (from Eq. 10-18)

$$v = \omega\ell = \sqrt{\frac{mg\ell^3}{I}}.$$ 

**ANALYZE** Using Table 10-2 and the parallel-axis theorem, the rotational inertia is $I = \frac{1}{3}m\ell^2$, so

$$v = \sqrt{3g\ell} = \sqrt{3(9.8 \text{ m/s}^2)(1.00 \text{ m})} = 5.42 \text{ m/s}.$$ 

**LEARN** The linear speed of a point on the meter stick depends on its distance from the axis of rotation. One may show that the speed of the center of mass is

$$v_{cm} = \omega(\ell/2) = \frac{1}{2}\sqrt{3g\ell}.$$ 

64. (a) We use the parallel-axis theorem to find the rotational inertia:

$$I = I_{cm} + Mh^2 = \frac{1}{2}MR^2 + Mh^2 = \frac{1}{2}(20 \text{ kg})(0.10 \text{ m})^2 + (20 \text{ kg})(0.50 \text{ m})^2 = 0.15 \text{ kg} \cdot \text{m}^2.$$
(b) Conservation of energy requires that $Mgh = \frac{1}{2}I\omega^2$, where $\omega$ is the angular speed of the cylinder as it passes through the lowest position. Therefore,

$$\omega = \sqrt{\frac{2Mgh}{I}} = \sqrt{\frac{2(20 \text{ kg})(9.8 \text{ m/s}^2)(0.050 \text{ m})}{0.15 \text{ kg} \cdot \text{m}^2}} \approx 11 \text{ rad/s}.$$ 

65. (a) We use conservation of mechanical energy to find an expression for $\omega^2$ as a function of the angle $\theta$ that the chimney makes with the vertical. The potential energy of the chimney is given by $U = Mgh$, where $M$ is its mass and $h$ is the altitude of its center of mass above the ground. When the chimney makes the angle $\theta$ with the vertical, $h = (H/2) \cos \theta$. Initially the potential energy is $U_i = Mg(H/2)$ and the kinetic energy is zero. The kinetic energy is $\frac{1}{2}I\omega^2$ when the chimney makes the angle $\theta$ with the vertical, where $I$ is its rotational inertia about its bottom edge. Conservation of energy then leads to

$$MgH/2 = Mg(H/2)\cos \theta + \frac{1}{2}I\omega^2 \Rightarrow \omega^2 = (MgH/I)(1 - \cos \theta).$$

The rotational inertia of the chimney about its base is $I = MH^2/3$ (found using Table 10-2(e) with the parallel axis theorem). Thus

$$\omega = \sqrt{\frac{3g}{H}(1 - \cos \theta)} = \sqrt{\frac{3(9.80 \text{ m/s}^2)}{55.0 \text{ m}}(1 - \cos 35.0^0)} \approx 0.311 \text{ rad/s}.$$ 

(b) The radial component of the acceleration of the chimney top is given by $a_r = H\omega^2$, so

$$a_r = 3g(1 - \cos \theta) = 3(9.80 \text{ m/s}^2)(1 - \cos 35.0^0) \approx 5.32 \text{ m/s}^2.$$ 

(c) The tangential component of the acceleration of the chimney top is given by $a_t = H\alpha$, where $\alpha$ is the angular acceleration. We are unable to use Table 10-1 since the acceleration is not uniform. Hence, we differentiate

$$\omega^2 = (3g/H)(1 - \cos \theta)$$

with respect to time, replacing $d\omega/dt$ with $\alpha$, and $d\theta/dt$ with $\omega$, and obtain

$$\frac{d\omega^2}{dt} = 2\omega\alpha = (3g/H)\omega \sin \theta \Rightarrow \alpha = (3g/2H)\sin \theta.$$ 

Consequently,

$$a_t = H\alpha = \frac{3g}{2} \sin \theta = \frac{3(9.80 \text{ m/s}^2)}{2} \sin 35.0^0 \approx 8.43 \text{ m/s}^2.$$
(d) The angle $\theta$ at which $a_t = g$ is the solution to $\frac{3\pi}{2} \sin \theta = g$. Thus, $\sin \theta = \frac{2}{3}$ and we obtain $\theta = 41.8^\circ$.

66. From Table 10-2, the rotational inertia of the spherical shell is $2MR^2/3$, so the kinetic energy (after the object has descended distance $h$) is

$$K = \frac{1}{2} \left( \frac{2}{3} MR^2 \right) \omega_{\text{sphere}}^2 + \frac{1}{2} I \omega_{\text{pulley}}^2 + \frac{1}{2} mv^2.$$ 

Since it started from rest, then this energy must be equal (in the absence of friction) to the potential energy $mgh$ with which the system started. We substitute $v/r$ for the pulley’s angular speed and $v/R$ for that of the sphere and solve for $v$.

$$v = \sqrt{\frac{mgh}{\frac{1}{2}m + \frac{1}{2} \frac{L}{r} + \frac{M}{r}}} = \sqrt{\frac{2gh}{1 + (1/mr^2) + (2M/3m)}} = 1.4 \text{ m/s}.$$ 

67. Using the parallel axis theorem and items (e) and (h) in Table 10-2, the rotational inertia is

$$I = \frac{1}{12} mL^2 + m(L/2)^2 + \frac{1}{2} mR^2 + m(R + L)^2 = 10.83mR^2,$$

where $L = 2R$ has been used. If we take the base of the rod to be at the coordinate origin ($x = 0, y = 0$) then the center of mass is at

$$y = \frac{mL/2 + m(L + R)}{m + m} = 2R.$$ 

Comparing the position shown in the textbook figure to its upside down (inverted) position shows that the change in center of mass position (in absolute value) is $|\Delta y| = 4R$. The corresponding loss in gravitational potential energy is converted into kinetic energy. Thus,

$$K = (2m)g(4R) \quad \Rightarrow \quad \omega = 9.82 \text{ rad/s}$$

where Eq. 10-34 has been used.

68. We choose ± directions such that the initial angular velocity is $\omega_0 = -317 \text{ rad/s}$ and the values for $\alpha$, $\tau$, and $F$ are positive.

(a) Combining Eq. 10-12 with Eq. 10-45 and Table 10-2(f) (and using the fact that $\omega = 0$) we arrive at the expression
\[ \tau = \left( \frac{2}{5} MR^2 \right) \left( -\frac{\omega_0}{t} \right) = -\frac{2}{5} \frac{MR^2 \omega_0}{t}. \]

With \( t = 15.5 \text{ s} \), \( R = 0.226 \text{ m} \), and \( M = 1.65 \text{ kg} \), we obtain \( \tau = 0.689 \text{ N} \cdot \text{m} \).

(b) From Eq. 10-40, we find \( F = \tau / R = 3.05 \text{ N} \).

(c) Using again the expression found in part (a), but this time with \( R = 0.854 \text{ m} \), we get \( \tau = 9.84 \text{ N} \cdot \text{m} \).

(d) Now, \( F = \tau / R = 11.5 \text{ N} \).

69. The volume of each disk is \( \pi r^2 h \) where we are using \( h \) to denote the thickness (which equals 0.00500 m). If we use \( R \) (which equals 0.0400 m) for the radius of the larger disk and \( r \) (which equals 0.0200 m) for the radius of the smaller one, then the mass of each is \( m = \rho \pi r^2 h \) and \( M = \rho \pi R^2 h \) where \( \rho = 1400 \text{ kg/m}^3 \) is the given density. We now use the parallel axis theorem as well as item (c) in Table 10-2 to obtain the rotation inertia of the two-disk assembly:

\[ I = \frac{1}{2} MR^2 + \frac{1}{2} m r^2 + m(r + R)^2 = \rho \pi h \left[ \frac{1}{2} R^4 + \frac{1}{2} r^4 + r^2 (r + R)^2 \right] = 6.16 \times 10^{-5} \text{ kg} \cdot \text{m}^2. \]

70. The wheel starts turning from rest (\( \omega_0 = 0 \)) at \( t = 0 \), and accelerates uniformly at \( \alpha = 2.00 \text{ rad/s}^2 \). Between \( t_1 \) and \( t_2 \) the wheel turns through \( \Delta \theta = 90.0 \text{ rad} \), where \( t_2 - t_1 = \Delta t = 3.00 \text{ s} \). We solve (b) first.

(b) We use Eq. 10-13 (with a slight change in notation) to describe the motion for \( t_1 \leq t \leq t_2 \):

\[ \Delta \theta = \omega_1 \Delta t + \frac{1}{2} \alpha (\Delta t)^2 \Rightarrow \omega_1 = \frac{\Delta \theta}{\Delta t} - \frac{\alpha \Delta t}{2} \]

which we plug into Eq. 10-12, set up to describe the motion during \( 0 \leq t \leq t_1 \):

\[ \omega_1 = \omega_0 + \alpha t_1 \Rightarrow \frac{\Delta \theta}{\Delta t} - \frac{\alpha \Delta t}{2} = \alpha t_1 \Rightarrow \frac{90.0}{3.00} - \frac{(2.00)(3.00)}{2} = (2.00)t_1 \]

yielding \( t_1 = 13.5 \text{ s} \).

(a) Plugging into our expression for \( \omega_1 \) (in previous part) we obtain

\[ \omega_1 = \frac{\Delta \theta}{\Delta t} - \frac{\alpha \Delta t}{2} = \frac{90.0}{3.00} - \frac{(2.00)(3.00)}{2} = 27.0 \text{ rad/s}. \]

71. THINK Since the string that connects the two blocks does not slip, the pulley rotates about its axel as the blocks move.
EXPRESS We choose positive coordinate directions (different choices for each item) so that each is accelerating positively, which will allow us to set \( a_2 = a_1 = R\alpha \) (for simplicity, we denote this as \( a \)). Thus, we choose rightward positive for \( m_2 = M \) (the block on the table), downward positive for \( m_1 = M \) (the block at the end of the string) and (somewhat unconventionally) clockwise for positive sense of disk rotation. This means that we interpret \( \theta \) given in the problem as a positive-valued quantity. Applying Newton’s second law to \( m_1, m_2 \) and (in the form of Eq. 10-45) to \( M \), respectively, we arrive at the following three equations (where we allow for the possibility of friction \( f_2 \) acting on \( m_2 \)):

\[
\begin{align*}
    m_1 g - T_1 &= m_1 a_1 \\
    T_2 - f_2 &= m_2 a_2 \\
    T_1 R - T_2 R &= I \alpha
\end{align*}
\]

ANALYZE (a) From Eq. 10-13 (with \( \omega_0 = 0 \)) we find the magnitude of the pulley’s angular acceleration to be

\[
\theta = \omega_0 t + \frac{1}{2} \alpha t^2 \quad \Rightarrow \quad \alpha = \frac{2\theta}{t^2} = \frac{2(0.130 \text{ rad})}{(0.0910 \text{ s})^2} = 31.4 \text{ rad/s}^2.
\]

(b) From the fact that \( a = R\alpha \) (noted above), the acceleration of the blocks is

\[
a = \frac{2R\theta}{t^2} = \frac{2(0.024 \text{ m})(0.130 \text{ rad})}{(0.0910 \text{ s})^2} = 0.754 \text{ m/s}^2.
\]

(c) From the first of the above equations, we find the string tension \( T_1 \) to be

\[
T_1 = m_1 (g - a_1) = M \left( g - \frac{2R\theta}{t^2} \right) = (6.20 \text{ kg}) \left( 9.80 \text{ m/s}^2 - \frac{2(0.024 \text{ m})(0.130 \text{ rad})}{(0.0910 \text{ s})^2} \right) = 56.1 \text{ N}.
\]

(d) From the last of the above equations, we obtain the second tension:

\[
T_2 = T_1 - \frac{I \alpha}{R} = 56.1 \text{ N} - \frac{(7.40 \times 10^{-4} \text{ kg} \cdot \text{m}^2)(31.4 \text{ rad/s}^2)}{0.024 \text{ m}} = 55.1 \text{ N}.
\]

LEARN The torque acting on the pulley is \( \tau = I \alpha = (T_1 - T_2)R \). If the pulley becomes massless, then \( I = 0 \) and we recover the expected result: \( T_1 = T_2 \).

72. (a) Constant angular acceleration kinematics can be used to compute the angular acceleration \( \alpha \). If \( \omega_0 \) is the initial angular velocity and \( t \) is the time to come to rest, then

\[
0 = \omega_0 + \alpha t,
\]

which gives
\[
\alpha = -\frac{\omega_s}{t} = -\frac{39.0 \text{ rev/s}}{32.0 \text{ s}} = -1.22 \text{ rev/s} = -7.66 \text{ rad/s}^2.
\]

(b) We use \( \tau = I\alpha \), where \( \tau \) is the torque and \( I \) is the rotational inertia. The contribution of the rod to \( I \) is \( M\ell^2/12 \) (Table 10-2(e)), where \( M \) is its mass and \( \ell \) is its length. The contribution of each ball is \( m(\ell/2)^2 \), where \( m \) is the mass of a ball. The total rotational inertia is

\[
I = \frac{M\ell^2}{12} + \frac{2m\ell^2}{4} = \frac{(6.40 \text{ kg})(1.20 \text{ m})^2}{12} + \frac{(1.06 \text{ kg})(1.20 \text{ m})^2}{2}
\]

which yields \( I = 1.53 \text{ kg} \cdot \text{m}^2 \). The torque, therefore, is

\[
\tau = (1.53 \text{ kg} \cdot \text{m}^2)(-7.66 \text{ rad/s}^2) = -11.7 \text{ N} \cdot \text{m}.
\]

(c) Since the system comes to rest the mechanical energy that is converted to thermal energy is simply the initial kinetic energy

\[
K_i = \frac{1}{2} I\omega_0^2 = \frac{1}{2}(1.53 \text{ kg} \cdot \text{m}^2)((2\pi)(39)) \text{ rad/s}^2 = 4.59 \times 10^4 \text{ J}.
\]

(d) We apply Eq. 10-13:

\[
\theta = \omega_0 t + \frac{1}{2} \alpha t^2 = (2\pi)(39) \text{ rad/s}(32.0 \text{ s}) + \frac{1}{2}(-7.66 \text{ rad/s}^2)(32.0 \text{ s})^2
\]

which yields 3920 rad or (dividing by \( 2\pi \)) 624 rev for the value of angular displacement \( \theta \).

(e) Only the mechanical energy that is converted to thermal energy can still be computed without additional information. It is \( 4.59 \times 10^4 \text{ J} \) no matter how \( \tau \) varies with time, as long as the system comes to rest.

73. The \textit{Hint} given in the problem would make the computation in part (a) very straightforward (without doing the integration as we show here), but we present this further level of detail in case that hint is not obvious or — simply — in case one wishes to see how the calculus supports our intuition.

(a) The (centripetal) force exerted on an infinitesimal portion of the blade with mass \( dm \) located a distance \( r \) from the rotational axis is (Newton’s second law) \( dF = (dm)\omega^2 r \), where \( dm \) can be written as \( (M/L)dr \) and the angular speed is

\[
\omega = (320)(2\pi/60) = 33.5 \text{ rad/s}.
\]

Thus for the entire blade of mass \( M \) and length \( L \) the total force is given by
\[
F = \int dF = \int \omega^2 r dm = \frac{M}{L} \int_0^L \omega^2 r dr = \frac{M \omega^2 L}{2} = \frac{(110 \text{ kg})(33.5 \text{ rad/s})^2 (7.80 \text{ m})}{2} = 4.81 \times 10^5 \text{ N}.
\]

(b) About its center of mass, the blade has \( I = ML^2 / 12 \) according to Table 10-2(e), and using the parallel-axis theorem to “move” the axis of rotation to its end-point, we find the rotational inertia becomes \( I = ML^2 / 3 \). Using Eq. 10-45, the torque (assumed constant) is

\[
\tau = I \alpha = \left( \frac{1}{3} ML^2 \right) \left( \frac{\Delta \omega}{\Delta t} \right) = \frac{1}{3} (110 \text{ kg})(7.8 \text{ m})^2 \left( \frac{33.5 \text{ rad/s}}{6.7 \text{ s}} \right) = 1.12 \times 10^4 \text{ N} \cdot \text{m}.
\]

(c) Using Eq. 10-52, the work done is

\[
W = \Delta K = \frac{1}{2} I \omega^2 - 0 = \frac{1}{2} \left( \frac{1}{3} ML^2 \right) \omega^2 = \frac{1}{6} (110 \text{ kg})(7.80 \text{ m})^2 (33.5 \text{ rad/s})^2 = 1.25 \times 10^6 \text{ J}.
\]

74. The angular displacements of disks \( A \) and \( B \) can be written as:

\[
\theta_A = \omega_A t, \quad \theta_B = \frac{1}{2} \alpha_B t^2.
\]

(a) The time when \( \theta_A = \theta_B \) is given by

\[
\omega_A t = \frac{1}{2} \alpha_B t^2 \quad \Rightarrow \quad t = \frac{2 \omega_A}{\alpha_B} = \frac{2(9.5 \text{ rad/s})}{(2.2 \text{ rad/s}^2)} = 8.6 \text{ s}.
\]

(b) The difference in the angular displacement is

\[
\Delta \theta = \theta_A - \theta_B = \omega_A t - \frac{1}{2} \alpha_B t^2 = 9.5t - 1.1t^2.
\]

For their reference lines to align momentarily, we only require \( \Delta \theta = 2\pi N \), where \( N \) is an integer. The quadratic equation can be readily solve to yield

\[
t_N = \frac{9.5 \pm \sqrt{(9.5)^2 - 4(1.1)(2\pi N)}}{2(1.1)} = \frac{9.5 \pm \sqrt{90.25 - 27.6N}}{2.2}.
\]

The solution \( t_0 = 8.63 \text{ s} \) (taking the positive root) coincides with the result obtained in (a), while \( t_0 = 0 \) (taking the negative root) is the moment when both disks begin to rotate. In fact, two solutions exist for \( N = 0, 1, 2, \) and 3.
75. The magnitude of torque is the product of the force magnitude and the distance from the pivot to the line of action of the force. In our case, it is the gravitational force that passes through the walker’s center of mass. Thus,

$$\tau = I\alpha = rF = rmg.$$ 

(a) Without the pole, with \(I = 15 \text{ kg} \cdot \text{m}^2\), the angular acceleration is

$$\alpha = \frac{rF}{I} = \frac{rmg}{I} = \frac{(0.050 \text{ m})(70 \text{ kg})(9.8 \text{ m/s}^2)}{15 \text{ kg} \cdot \text{m}^2} = 2.3 \text{ rad/s}^2.$$ 

(b) When the walker carries a pole, the torque due to the gravitational force through the pole’s center of mass opposes the torque due to the gravitational force that passes through the walker’s center of mass. Therefore,

$$\tau_{\text{net}} = \sum_i r_i F_i = (0.050 \text{ m})(70 \text{ kg})(9.8 \text{ m/s}^2) - (0.10 \text{ m})(14 \text{ kg})(9.8 \text{ m/s}^2) = 20.58 \text{ N} \cdot \text{m},$$ 

and the resulting angular acceleration is

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{20.58 \text{ N} \cdot \text{m}}{15 \text{ kg} \cdot \text{m}^2} \approx 1.4 \text{ rad/s}^2.$$ 

76. The motion consists of two stages. The first, the interval \(0 \leq t \leq 20 \text{ s}\), consists of constant angular acceleration given by

$$\alpha = \frac{5.0 \text{ rad/s}}{2.0 \text{ s}} = 2.5 \text{ rad/s}^2.$$ 

The second stage, \(20 < t \leq 40 \text{ s}\), consists of constant angular velocity \(\omega = \Delta \theta / \Delta t\). Analyzing the first stage, we find

$$\theta_1 = \frac{1}{2} \alpha t^2 \bigg|_{t=20} = 500 \text{ rad}, \quad \omega = \alpha t \bigg|_{t=20} = 50 \text{ rad/s}.$$ 

Analyzing the second stage, we obtain

$$\theta_2 = \theta_1 + \alpha \Delta t = 500 \text{ rad} + (50 \text{ rad/s})(20 \text{ s}) = 1.5 \times 10^3 \text{ rad}.$$ 

77. THINK The record turntable comes to a stop due to a constant angular acceleration. We apply equations given in Table 10-1 to analyze the rotational motion.
EXPRESS We take the sense of initial rotation to be positive. Then, with \( \omega_0 > 0 \) and \( \omega = 0 \) (since it stops at time \( t \)), our angular acceleration is negative-valued. The angular acceleration is constant, so we can apply Eq. 10-12 \( (\omega = \omega_0 + \alpha t) \), which gives \( \alpha = (\omega - \omega_0)/t \). Similarly, the angular displacement can be found by using Eq. 10-13:
\[
\theta = \theta_0 + \omega_0 t + \frac{1}{2} \alpha t^2.
\]

ANALYZE (a) To obtain the requested units, we use \( t = 30 \text{ s} = 0.50 \text{ min} \). With \( \omega_0 = 33.33 \text{ rev/min} \), we find the angular acceleration to be
\[
\alpha = -\frac{33.33 \text{ rev/min}}{0.50 \text{ min}} = -66.7 \text{ rev/min}^2 \approx -67 \text{ rev/min}^2.
\]
(b) Substituting the value of \( \alpha \) obtained above into Eq. 10-13, we get
\[
\theta = \omega_0 t + \frac{1}{2} \alpha t^2 = (33.33 \text{ rev/min})(0.50 \text{ min}) + \frac{1}{2}(-66.7 \text{ rev/min}^2)(0.50 \text{ min})^2 = 8.33 \text{ rev}.
\]

LEARN To solve for the angular displacement in (b), we may also use Eq. 10-15:
\[
\theta = \frac{1}{2} (\omega_0 + \omega)t = \frac{1}{2} (33.33 \text{ rev/min} + 0)(0.50 \text{ min}) = 8.33 \text{ rev}.
\]

78. We use conservation of mechanical energy. The center of mass is at the midpoint of the cross bar of the block and it drops by \( L/2 \), where \( L \) is the length of any one of the rods. The gravitational potential energy decreases by \( MgL/2 \), where \( M \) is the mass of the body. The initial kinetic energy is zero and the final kinetic energy may be written \( \frac{1}{2} I \omega^2 \), where \( I \) is the rotational inertia of the body and \( \omega \) is its angular velocity when it is vertical. Thus,
\[
0 = -MgL/2 + \frac{1}{2} I \omega^2 \Rightarrow \omega = \sqrt{\frac{MgL}{I}}.
\]

Since the rods are thin the one along the axis of rotation does not contribute to the rotational inertia. All points on the other leg are the same distance from the axis of rotation, so that leg contributes \( (M/3)L^2 \), where \( M/3 \) is its mass. The cross bar is a rod that rotates around one end, so its contribution is \( (M/3)L^2/3 = ML^2/9 \). The total rotational inertia is
\[
I = (ML^2/3) + (ML^2/9) = 4ML^2/9.
\]

Consequently, the angular velocity is
\[
\omega = \sqrt{\frac{MgL}{I}} = \sqrt{\frac{MgL}{4ML^2/9}} = \frac{9g}{4L} = \sqrt{\frac{9(9.800 \text{ m/s}^2)}{4(0.600 \text{ m})}} = 6.06 \text{ rad/s}.
\]
79. **THINK** In this problem we compare the rotational inertia between a solid cylinder and a hoop.

**EXPRESS** According to Table 10-2, the rotational inertia formulas for a cylinder of radius \( R \) and mass \( M \), and a hoop of radius \( r \) and mass \( M \) are

\[
I_c = \frac{1}{2} M R^2, \quad I_H = Mr^2.
\]

Equating \( I_c = I_H \) allows us to deduce the relationship between \( r \) and \( R \).

**ANALYZE** (a) Since both the cylinder and the hoop have the same mass, then they will have the same rotational inertia (\( I_c = I_H \)) if

\[
R^2 / 2 = r^2 \quad \Rightarrow \quad r = R / \sqrt{2}.
\]

(b) We require the rotational inertia of any given body to be written as \( I = Mk^2 \), where \( M \) is the mass of the given body and \( k \) is the radius of the “equivalent hoop.” It follows directly that \( k = \sqrt{I / M} \).

**LEARN** Listed below are some examples of equivalent hoop and their radii:

\[
I_c = \frac{1}{2} M R^2 = M (R / \sqrt{2})^2 \quad \Rightarrow \quad k_c = R / \sqrt{2}
\]

\[
I_s = \frac{2}{5} M R^2 = M \left( \frac{2}{\sqrt{5}} R \right)^2 \quad \Rightarrow \quad k_s = \frac{\sqrt{2}}{\sqrt{5}} R
\]

80. (a) Using Eq. 10-15, we have \( \omega_1 = \frac{1}{2} (\omega_1 + \omega_2)(6.00 \text{ s}) \). With \( \omega_2 = 15.0 \text{ rad/s} \), then \( \omega_1 = 5.00 \text{ rad/s} \).

(b) Eq. 10-12 gives \( \alpha = (15.0 \text{ rad/s} - 5.0 \text{ rad/s})/ (6.00 \text{ s}) = 1.67 \text{ rad/s}^2 \).

(c) Interpreting \( \omega \) now as \( \omega_1 \) and \( \theta \) as \( \theta_1 = 10.0 \text{ rad} \) (and \( \omega_0 = 0 \)) Eq. 10-14 leads to

\[
\theta_o = - \frac{\omega_1^2}{2 \alpha} + \theta_1 = 2.50 \text{ rad}.
\]

81. The center of mass is initially at height \( h = \frac{L}{2} \sin 40^\circ \) when the system is released (where \( L = 2.0 \text{ m} \)). The corresponding potential energy \( Mgh \) (where \( M = 1.5 \text{ kg} \)) becomes rotational kinetic energy \( \frac{1}{2} I \omega^2 \) as it passes the horizontal position (where \( I \) is the rotational inertia about the pin). Using Table 10-2 (e) and the parallel axis theorem, we find

\[
I = \frac{1}{12} ML^2 + M (L / 2)^2 = \frac{1}{3} ML^2.
\]
Therefore,
\[ M g \frac{L}{2} \sin 40^\circ = \frac{1}{2} \left( \frac{1}{3} M L^2 \right) \omega^2 \Rightarrow \omega = \sqrt{\frac{3g \sin 40^\circ}{L}} = 3.1 \text{ rad/s}. \]

82. The rotational inertia of the passengers is (to a good approximation) given by Eq. 10-53: \( I = \sum m R^2 = N m R^2 \) where \( N \) is the number of people and \( m \) is the (estimated) mass per person. We apply Eq. 10-52:
\[ W = \frac{1}{2} I \omega^2 = \frac{1}{2} N m R^2 \omega^2 \]
where \( R = 38 \text{ m} \) and \( N = 36 \times 60 = 2160 \) persons. The rotation rate is constant so that \( \omega = \theta t \) which leads to \( \omega = 2\pi/120 = 0.052 \text{ rad/s} \). The mass (in kg) of the average person is probably in the range \( 50 \leq m \leq 100 \), so the work should be in the range
\[ \frac{1}{2} (2160)(50)(38)^2 (0.052)^2 \leq W \leq \frac{1}{2} (2160)(100)(38)^2 (0.052)^2 \]
\[ 2 \times 10^5 \text{ J} \leq W \leq 4 \times 10^5 \text{ J}. \]

83. We choose positive coordinate directions (different choices for each item) so that each is accelerating positively, which will allow us to set \( a_1 = a_2 = R \alpha \) (for simplicity, we denote this as \( a \)). Thus, we choose upward positive for \( m_1 \), downward positive for \( m_2 \), and (somewhat unconventionally) clockwise for positive sense of disk rotation. Applying Newton’s second law to \( m_1 m_2 \) and (in the form of Eq. 10-45) to \( M \), respectively, we arrive at the following three equations.

\[ T_1 - m_1 g = m_1 a_1 \]
\[ m_2 g - T_2 = m_2 a_2 \]
\[ T_2 R - T_1 R = I \alpha \]

(a) The rotational inertia of the disk is \( I = \frac{1}{2} M R^2 \) (Table 10-2(c)), so we divide the third equation (above) by \( R \), add them all, and use the earlier equality among accelerations — to obtain:
\[ m_2 g - m_1 g = \left( m_1 + m_2 + \frac{1}{2} M \right) a \]
which yields \( a = \frac{4}{25} g = 1.57 \text{ m/s}^2 \).

(b) Plugging back in to the first equation, we find
\[ T_1 = \frac{29}{25} m_1 g = 4.55 \text{ N} \]
where it is important in this step to have the mass in SI units: \( m_1 = 0.40 \text{ kg} \).

(c) Similarly, with \( m_2 = 0.60 \text{ kg} \), we find \( T_2 = \frac{5}{6} m_2 g = 4.94 \text{ N} \).

84. (a) The longitudinal separation between Helsinki and the explosion site is \( \Delta \theta = 102^\circ - 25^\circ = 77^\circ \). The spin of the Earth is constant at

\[
\omega = \frac{1 \text{ rev}}{1 \text{ day}} = \frac{360^\circ}{24 \text{ h}}
\]

so that an angular displacement of \( \Delta \theta \) corresponds to a time interval of

\[
\Delta t = (77^\circ) \left(\frac{24 \text{ h}}{360^\circ}\right) = 5.1 \text{ h}.
\]

(b) Now \( \Delta \theta = 102^\circ - (-20^\circ) = 122^\circ \) so the required time shift would be

\[
\Delta t = (122^\circ) \left(\frac{24 \text{ h}}{360^\circ}\right) = 8.1 \text{ h}.
\]

85. To get the time to reach the maximum height, we use Eq. 4-23, setting the left-hand side to zero. Thus, we find

\[
t = \frac{(60 \text{ m/s}) \sin(20^\circ)}{9.8 \text{ m/s}^2} = 2.094 \text{ s}.
\]

Then (assuming \( \alpha = 0 \)) Eq. 10-13 gives

\[
\theta - \theta_0 = \alpha \beta t = (90 \text{ rad/s})(2.094 \text{ s}) = 188 \text{ rad},
\]

which is equivalent to roughly 30 rev.

86. In the calculation below, \( M_1 \) and \( M_2 \) are the ring masses, \( R_{1i} \) and \( R_{2i} \) are their inner radii, and \( R_{1o} \) and \( R_{2o} \) are their outer radii. Referring to item (b) in Table 10-2, we compute

\[
I = \frac{1}{2} M_1 (R_{1i}^2 + R_{1o}^2) + \frac{1}{2} M_2 (R_{2i}^2 + R_{2o}^2) = 0.00346 \text{ kg} \cdot \text{m}^2.
\]

Thus, with Eq. 10-38 \( (\tau = rF \text{ where } r = R_{2o} \) and \( \tau = I \alpha \) (Eq. 10-45), we find

\[
\alpha = \frac{(0.140)(12.0)}{0.00346} = 485 \text{ rad/s}^2.
\]

Then Eq. 10-12 gives \( \omega = \alpha t = 146 \text{ rad/s} \).
87. We choose positive coordinate directions so that each is accelerating positively, which will allow us to set \( a_{\text{box}} = R\alpha \) (for simplicity, we denote this as \( a \)). Thus, we choose downhill positive for the \( m = 2.0 \) kg box and (as is conventional) counterclockwise for positive sense of wheel rotation. Applying Newton’s second law to the box and (in the form of Eq. 10-45) to the wheel, respectively, we arrive at the following two equations (using \( \theta \) as the incline angle 20°, not as the angular displacement of the wheel).

\[
mg \sin \theta - T = ma
\]

\[
TR = I\alpha
\]

Since the problem gives \( a = 2.0 \) m/s\(^2\), the first equation gives the tension \( T = m (g \sin \theta - a) = 2.7 \) N. Plugging this and \( R = 0.20 \) m into the second equation (along with the fact that \( \alpha = a/R \)) we find the rotational inertia

\[
I = TR^2/a = 0.054 \text{ kg} \cdot \text{m}^2.
\]

88. (a) We use \( \tau = I\alpha \), where \( \tau \) is the net torque acting on the shell, \( I \) is the rotational inertia of the shell, and \( \alpha \) is its angular acceleration. Therefore,

\[
I = \frac{\tau}{\alpha} = \frac{960 \text{ N} \cdot \text{m}}{6.20 \text{ rad} / \text{s}^2} = 155 \text{ kg} \cdot \text{m}^2.
\]

(b) The rotational inertia of the shell is given by \( I = (2/3)MR^2 \) (see Table 10-2 of the text). This implies

\[
M = \frac{3I}{2R^2} = \frac{3(155 \text{ kg} \cdot \text{m}^2)}{2(1.90 \text{ m})^2} = 64.4 \text{ kg}.
\]

89. Equation 10-40 leads to \( \tau = mgr = (70 \) kg \( ) (9.8 \) m/s\(^2\) \( ) (0.20 \) m) \( = 1.4 \times 10^2 \) N·m.

90. (a) Equation 10-12 leads to \( \alpha = -\omega_o / t = -(25.0 \) rad/s\)\()/(20.0 \) s) \( = -1.25 \) rad/s\(^2\).

(b) Equation 10-15 leads to \( \theta = \frac{1}{2} \omega_o t = \frac{1}{2} (25.0 \) rad/s\)\()(20.0 \) s) \( = 250 \) rad.

(c) Dividing the previous result by \( 2\pi \) we obtain \( \theta = 39.8 \) rev.

91. **THINK** As the box falls, gravitational force gives rise to a torque that causes the wheel to rotate.

**EXPRESS** We employ energy methods to solve this problem; thus, considerations of positive versus negative sense (regarding the rotation of the wheel) are not relevant.
(a) The speed of the box is related to the angular speed of the wheel by \( v = R \omega \), where \( K_{\text{box}} = \frac{1}{2} m_{\text{box}} v^2 / 2 \). The rotational kinetic energy of the wheel is \( K_{\text{rot}} = \frac{1}{2} I \omega^2 / 2 \).

**ANALYZE**

(a) With \( K_{\text{box}} = 0.60 \text{ J} \), we find the speed of the box to be

\[
K_{\text{box}} = \frac{1}{2} m_{\text{box}} v^2 \Rightarrow v = \sqrt{\frac{2K_{\text{box}}}{m_{\text{box}}}} = \sqrt{\frac{2(6.0 \text{ J})}{6.0 \text{ kg}}} = 1.41 \text{ m/s ,}
\]

implying that the angular speed is \( \omega = \frac{(1.41 \text{ m/s})}{(0.20 \text{ m})} = 7.07 \text{ rad/s} \). Thus, the kinetic energy of rotation is

\[
K_{\text{rot}} = \frac{1}{2} I \omega^2 = \frac{1}{2} (0.40 \text{ kg m}^2)(7.07 \text{ rad/s})^2 = 10.0 \text{ J}.
\]

(b) Since it was released from rest, we will take the initial position to be our reference point for gravitational potential. Energy conservation requires

\[
K_0 + U_0 = K + U \quad \Rightarrow \quad 0 + 0 = (6.0 \text{ J} + 10.0 \text{ J}) + m_{\text{box}} g (-h).
\]

Therefore,

\[
h = \frac{K}{m_{\text{box}} g} = \frac{6.0 \text{ J} + 10.0 \text{ J}}{(6.0 \text{ kg})(9.8 \text{ m/s}^2)} = 0.27 \text{ m}.
\]

**LEARN**

As the box falls, its gravitational potential energy gets converted into kinetic energy of the box as well as rotational kinetic energy of the wheel; the total energy remains conserved.

92. (a) The time for one revolution is the circumference of the orbit divided by the speed \( v \) of the Sun: \( T = \frac{2\pi R}{v} \), where \( R \) is the radius of the orbit. We convert the radius:

\[
R = (2.3 \times 10^4 \text{ ly})(9.46 \times 10^{12} \text{ km/ly}) = 2.18 \times 10^{17} \text{ km}
\]

where the ly ↔ km conversion can be found in Appendix D or figured “from basics” (knowing the speed of light). Therefore, we obtain

\[
T = \frac{2\pi (2.18 \times 10^{17} \text{ km})}{250 \text{ km/s}} = 5.5 \times 10^{15} \text{ s}.
\]

(b) The number of revolutions \( N \) is the total time \( t \) divided by the time \( T \) for one revolution; that is, \( N = t/T \). We convert the total time from years to seconds and obtain

\[
N = \frac{(4.5 \times 10^9 \text{ y})(3.16 \times 10^7 \text{ s/y})}{5.5 \times 10^{15} \text{ s}} = 26.
\]
93. **THINK** The applied force $P$ accelerates the block. In addition, it gives rise to a torque that causes the wheel to undergo angular acceleration.

**EXPRESS** We take rightward to be positive for the block and clockwise negative for the wheel (as is conventional). With this convention, we note that the tangential acceleration of the wheel is of opposite sign from the block’s acceleration (which we simply denote as $a$); that is, $a_t = -a$. Applying Newton’s second law to the block leads to $P - T = ma$, where $T$ is the tension in the cord. Similarly, applying Newton’s second law (for rotation) to the wheel leads to $-TR = I\alpha$. Noting that $R\alpha = a_t = -a$, we multiply this equation by $R$ and obtain

$$-TR^2 = -Ia \Rightarrow T = a \frac{I}{R^2}. $$

Adding this to the above equation (for the block) leads to $P = (m+I/R^2)a$. Thus, the angular acceleration is

$$\alpha = -\frac{a}{R} = -\frac{P}{(m+I/R^2)R}$$

**ANALYZE** With $m = 2.0 \text{ kg}$, $I = 0.050 \text{ kg} \cdot \text{m}^2$, $P = 3.0 \text{ N}$ and $R = 0.20 \text{ m}$, we find

$$\alpha = -\frac{3.0 \text{ N}}{(2.0 \text{ kg} + (0.050 \text{ kg} \cdot \text{m}^2)/(0.20 \text{ m})^2)(0.20 \text{ m})} = -4.62 \text{ rad/s}^2,$$

or $|\alpha| = 4.62 \text{ rad/s}^2$.

**LEARN** The greater the applied force $P$, the greater the (magnitude of) angular acceleration. Note that the negative sign in $\alpha$ should not be mistaken for a deceleration; it simply indicates the clockwise sense to the motion.

94. First, we convert the angular velocity: $\omega = (2000 \text{ rev/min})(2\pi/60) = 209 \text{ rad/s}$. Also, we convert the plane’s speed to SI units: $(480)(1000/3600) = 133 \text{ m/s}$. We use Eq. 10-18 in part (a) and (implicitly) Eq. 4-39 in part (b).

(a) The speed of the tip as seen by the pilot is $v_t = \omega r = (209 \text{ rad/s})(1.5 \text{ m}) = 314 \text{ m/s}$, which (since the radius is given to only two significant figures) we write as $v_t = 3.1 \times 10^2 \text{ m/s}$.

(b) The plane’s velocity $\bar{v}_p$ and the velocity of the tip $\bar{v}_t$ (found in the plane’s frame of reference), in any of the tip’s positions, must be perpendicular to each other. Thus, the speed as seen by an observer on the ground is

$$v = \sqrt{v^2_p + v^2_t} = \sqrt{(133 \text{ m/s})^2 + (314 \text{ m/s})^2} = 3.4 \times 10^2 \text{ m/s}.$$
95. The distances from \( P \) to the particles are as follows:

\[
\begin{align*}
    r_1 &= a \text{ for } m_1 = 2M \text{ (lower left)} \\
    r_2 &= \sqrt{b^2 - a^2} \text{ for } m_2 = M \text{ (top)} \\
    r_3 &= a \text{ for } m_3 = 2M \text{ (lower right)}
\end{align*}
\]

The rotational inertia of the system about \( P \) is

\[
I = \sum_{i=1}^{3} m_i r_i^2 = \left(3a^2 + b^2\right)M,
\]

which yields \( I = 0.208 \text{ kg} \cdot \text{m}^2 \) for \( M = 0.40 \text{ kg}, a = 0.30 \text{ m}, \text{ and } b = 0.50 \text{ m}. \) Applying Eq. 10-52, we find

\[
W = \frac{1}{2} I \omega^2 = \frac{1}{2} \left(0.208 \text{ kg} \cdot \text{m}^2\right)(5.0 \text{ rad/s})^2 = 2.6 \text{ J}.
\]

96. In the figure below, we show a pull tab of a beverage can. Since the tab is pivoted, when pulling on one end upward with a force \( \vec{F}_1 \), a force \( \vec{F}_2 \) will be exerted on the other end. The torque produced by \( \vec{F}_1 \) must be balanced by the torque produced by \( \vec{F}_2 \) so that the tab does not rotate.

The two forces are related by

\[ r_1 F_1 = r_2 F_2 \]

where \( r_1 \approx 1.8 \text{ cm} \) and \( r_2 \approx 0.73 \text{ cm} \). Thus, if \( F_1 = 10 \text{ N}, \)

\[
F_2 = \left(\frac{r_1}{r_2}\right) F_1 = \left(\frac{1.8 \text{ cm}}{0.73 \text{ cm}}\right)(10 \text{ N}) \approx 25 \text{ N}.
\]

97. The centripetal acceleration at a point \( P \) that is \( r \) away from the axis of rotation is given by Eq. 10-23: \( a = v^2/r = \omega^2 r \), where \( v = \omega r \), with \( \omega = 2000 \text{ rev/min} \approx 209.4 \text{ rad/s} \).

(a) If points \( A \) and \( P \) are at a radial distance \( r_A = 1.50 \text{ m} \) and \( r = 0.150 \text{ m} \) from the axis, the difference in their acceleration is

\[
\Delta a = a_A - a = \omega^2 (r_A^2 - r^2) = (209.4 \text{ rad/s})^2 (1.50 \text{ m} - 0.150 \text{ m}) \approx 5.92 \times 10^4 \text{ m/s}^2.
\]
(b) The slope is given by \( \frac{a}{r} = \omega^2 = 4.39 \times 10^4 \text{ rad/s}^2 \).

98. Let \( T \) be the tension on the rope. From Newton’s second law, we have

\[
T - mg = ma \quad \Rightarrow \quad T = m(g + a).
\]

Since the box has an upward acceleration \( a = 0.80 \text{ m/s}^2 \), the tension is given by

\[
T = (30 \text{ kg})(9.8 \text{ m/s}^2 + 0.8 \text{ m/s}^2) = 318 \text{ N}.
\]

The rotation of the device is described by \( F_{\text{app}} R - Tr = I \alpha = I a / r \). The moment of inertia can then be obtained as

\[
I = \frac{r(F_{\text{app}} R - Tr)}{a} = \frac{(0.20 \text{ m})[(140 \text{ N})(0.50 \text{ m}) - (318 \text{ N})(0.20 \text{ m})]}{0.80 \text{ m/s}^2} = 1.6 \text{ kg m}^2.
\]

99. (a) With \( r = 0.780 \text{ m} \), the rotational inertia is

\[
I = Mr^2 = (1.30 \text{ kg})(0.780 \text{ m})^2 = 0.791 \text{ kg m}^2.
\]

(b) The torque that must be applied to counteract the effect of the drag is

\[
\tau = rf = (0.780 \text{ m})(2.30 \times 10^{-2} \text{ N}) = 1.79 \times 10^{-2} \text{ N m}.
\]

100. We make use of Table 10-2(e) as well as the parallel-axis theorem, Eq. 10-34, where needed. We use \( l \) (as a subscript) to refer to the long rod and \( s \) to refer to the short rod.

(a) The rotational inertia is

\[
I = I_s + I_l = \frac{1}{12} m_s L_s^2 + \frac{1}{3} m_l L_l^2 = 0.019 \text{ kg m}^2.
\]

(b) We note that the center of the short rod is a distance of \( h = 0.25 \text{ m} \) from the axis. The rotational inertia is

\[
I = I_s + I_l = \frac{1}{12} m_s L_s^2 + m_l h^2 + \frac{1}{12} m_l L_l^2
\]

which again yields \( I = 0.019 \text{ kg m}^2 \).

101. (a) The linear speed of a point on belt 1 is

\[
v_1 = r_1 \omega = (15 \text{ cm})(10 \text{ rad/s}) = 1.5 \times 10^2 \text{ cm/s}.
\]
(b) The angular speed of pulley \( B \) is

\[
r_A \omega_A = r_B \omega_B \quad \Rightarrow \quad \omega_B = \frac{r_A \omega_A}{r_B} = \left( \frac{15 \text{ cm}}{10 \text{ cm}} \right)(10 \text{ rad/s}) = 15 \text{ rad/s}.
\]

(c) Since the two pulleys are rigidly attached to each other, the angular speed of pulley \( B' \) is the same as that of pulley \( B \), that is, \( \omega'_B = 15 \text{ rad/s} \).

(d) The linear speed of a point on belt 2 is

\[
v_2 = r_B \omega'_B = (5 \text{ cm})(15 \text{ rad/s}) = 75 \text{ cm/s}.
\]

(e) The angular speed of pulley \( C \) is

\[
r_C \omega_C = r_B \omega'_B \quad \Rightarrow \quad \omega_C = \frac{r_B \omega'_B}{r_C} = \left( \frac{5 \text{ cm}}{25 \text{ cm}} \right)(15 \text{ rad/s}) = 3.0 \text{ rad/s}
\]

102. (a) The rotational inertia relative to the specified axis is

\[
I = \sum m_i r_i^2 = (2M)L^2 + (2M)L^2 + M(2L)^2
\]

which is found to be \( I = 4.6 \text{ kg} \cdot \text{m}^2 \). Then, with \( \omega = 1.2 \text{ rad/s} \), we obtain the kinetic energy from Eq. 10-34:

\[
K = \frac{1}{2} I \omega^2 = 3.3 \text{ J}.
\]

(b) In this case the axis of rotation would appear as a standard \( y \) axis with origin at \( P \). Each of the \( 2M \) balls are a distance of \( r = L \cos 30^\circ \) from that axis. Thus, the rotational inertia in this case is

\[
I = \sum m_i r_i^2 = (2M)r^2 + (2M)r^2 + M(2L)^2
\]

which is found to be \( I = 4.0 \text{ kg} \cdot \text{m}^2 \). Again, from Eq. 10-34 we obtain the kinetic energy

\[
K = \frac{1}{2} I \omega^2 = 2.9 \text{ J}.
\]

103. We make use of Table 10-2(e) and the parallel-axis theorem in Eq. 10-36.

(a) The moment of inertia is

\[
I = \frac{1}{12} ML^2 + Mh^2 = \frac{1}{12}(3.0 \text{ kg})(4.0 \text{ m})^2 + (3.0 \text{ kg})(1.0 \text{ m})^2 = 7.0 \text{ kg} \cdot \text{m}^2.
\]
(b) The rotational kinetic energy is
\[ \frac{1}{2} I \omega^2 \Rightarrow \omega = \sqrt{\frac{2K_{rot}}{I}} = \sqrt{\frac{2(20 \text{ J})}{7 \text{ kg} \cdot \text{m}^2}} = 2.4 \text{ rad/s}. \]

The linear speed of the end B is given by \( v_B = \omega r_{AB} = (2.4 \text{ rad/s})(3.00 \text{ m}) = 7.2 \text{ m/s} \), where \( r_{AB} \) is the distance between A and B.

(c) The maximum angle \( \theta \) is attained when all the rotational kinetic energy is transformed into potential energy. Moving from the vertical position (\( \theta = 0 \)) to the maximum angle \( \theta \), the center of mass is elevated by \( \Delta y = d_{AC}(1 - \cos \theta) \), where \( d_{AC} = 1.00 \text{ m} \) is the distance between A and the center of mass of the rod. Thus, the change in potential energy is
\[ \Delta U = mg \Delta y = mgd_{AC}(1 - \cos \theta) \Rightarrow 20 \text{ J} = (3.0 \text{ kg})(9.8 \text{ m/s}^2)(1.0 \text{ m})(1 - \cos \theta) \]
which yields \( \cos \theta = 0.32 \), or \( \theta \approx 71^\circ \).

104. (a) The particle at A has \( r = 0 \) with respect to the axis of rotation. The particle at B is \( r = L = 0.50 \text{ m} \) from the axis; similarly for the particle directly above A in the figure. The particle diagonally opposite A is a distance \( r = \sqrt{2}L = 0.71 \text{ m} \) from the axis. Therefore,
\[ I = \sum m_i r_i^2 = 2mL^2 + m\left(\sqrt{2}L\right)^2 = 0.20 \text{ kg} \cdot \text{m}^2. \]

(b) One imagines rotating the figure (about point A) clockwise by 90° and noting that the center of mass has fallen a distance equal to \( L \) as a result. If we let our reference position for gravitational potential be the height of the center of mass at the instant \( AB \) swings through vertical orientation, then
\[ K_0 + U_0 = K + U \Rightarrow 0 + (4m)gh_0 = K + 0. \]
Since \( h_0 = L = 0.50 \text{ m} \), we find \( K = 3.9 \text{ J} \). Then, using Eq. 10-34, we obtain
\[ K = \frac{1}{2}I_{A_1} \omega^2 \Rightarrow \omega = 6.3 \text{ rad/s}. \]

105. (a) We apply Eq. 10-18, using the subscript J for the Jeep.
\[ \omega = \frac{v_J}{r_J} = \frac{114 \text{ km/h}}{0.100 \text{ km}} \]
which yields 1140 rad/h or (dividing by 3600) 0.32 rad/s for the value of the angular speed \( \omega \).
(b) Since the cheetah has the same angular speed, we again apply Eq. 10-18, using the subscript \( c \) for the cheetah.

\[
v_c = r_c \omega = (92 \text{ m}) (1140 \text{ rad/h}) = 1.048 \times 10^5 \text{ m/h} \approx 1.0 \times 10^2 \text{ km/h}
\]

for the cheetah’s speed.

106. Using Eq. 10-7 and Eq. 10-18, the average angular acceleration is

\[
\alpha_{avg} = \frac{\Delta \omega}{\Delta t} = \frac{\Delta v}{r \Delta t} = \frac{25 - 12}{(0.75/2)(6.2)} = 5.6 \text{ rad/s}^2.
\]

107. (a) Using Eq. 10-1, the angular displacement is

\[
\theta = \frac{5.6 \text{ m}}{8.0 \times 10^{-2} \text{ m}} = 1.4 \times 10^2 \text{ rad}.
\]

(b) We use \( \theta = \frac{1}{2} \alpha t^2 \) (Eq. 10-13) to obtain \( t \):

\[
t = \sqrt{\frac{2\theta}{\alpha}} = \sqrt{\frac{2(1.4 \times 10^2 \text{ rad})}{1.5 \text{ rad/s}^2}} = 14 \text{ s}.
\]

108. (a) We obtain

\[
\omega = \frac{(33.33 \text{ rev/min}) (2\pi \text{ rad/rev})}{60 \text{ s/min}} = 3.5 \text{ rad/s}.
\]

(b) Using Eq. 10-18, we have \( v = r \omega = (15)(3.49) = 52 \text{ cm/s} \).

(c) Similarly, when \( r = 7.4 \text{ cm} \) we find \( v = r \omega = 26 \text{ cm/s} \). The goal of this exercise is to observe what is and is not the same at different locations on a body in rotational motion (\( \omega \) is the same, \( v \) is not), as well as to emphasize the importance of radians when working with equations such as Eq. 10-18.
