# Lectures 12: Bootstrap II.

bootstrap and its statistics reviewed

#### Method 3: Bootstrap resampling of the data

- We applied some end-to-end process to a data set and got a number f out
- The data set was drawn from a <u>population</u> of repetitions of the identical experiment
  - which we don't get to see, unfortunately
  - we see only a sample of the population
- We'd like to draw new data sets from the population, reapply the process, and see the distribution of answers
  - this would tell us how accurate the original answer, on average, was
  - but we can't: we don't have access to the population
- However, the data set itself is an estimate of the population pdf!
  - in fact, it's the only estimate we've got!
- So we draw from the data set with replacement many "fake" data sets of equal size, and carry out the proposed program
  - does this sound crazy? for a long time many people thought so!
  - Bootstrap theorem [glossing over technical assumptions]: The distribution of any resampled quantity around its full-data-set value estimates (naively: "asymptotically has the same histogram as") the distribution of the data set value around the population value.

## The Empirical density function

Statistical inference concerns learning from experience: we observe a random sample  $\mathbf{x} = (x_1, x_2, \dots, x_n)$  and wish to infer properties of the complete population  $\mathcal{X}$  that yielded the sample. A complete knowledge is obtained from the population density function F(.) from which  $\mathbf{x}$  has been generated  $F \rightsquigarrow \mathbf{x} = (x_1, x_2, \dots, x_n)$ 

#### Definition

The empirical density function  $\hat{F}(.)$  is defined as:

$$\hat{F}(x) = \frac{1}{n} \sum_{i=1}^{n} \delta(x - x_i)$$

where  $\delta(\cdot)$  is the Dirac delta function. So the probability of  $x = x_j$  is :

$$\int \hat{F}(x_j) dx = \int \frac{1}{n} \sum_{i=1}^n \delta(x_j - x_i) dx = \begin{cases} \frac{1}{n}, x_j \in \{x_1, \dots, x_n\} \\ 0, \text{ otherwise} \end{cases}$$

### statistics reviewed

### Parameters

#### Definition

A parameter,  $\theta$ , is a function of the probability density function (p.d.f.) *F*, e.g.:

$$\theta = t(F)$$

#### if $\theta$ is the mean

$$\theta = \mathbb{E}_F(x) = \int_{-\infty}^{+\infty} x F(x) dx = \mu_F$$

### if $\theta$ is the variance

$$\theta = \mathbb{E}_F[(x - \mu_F)^2] = \int_{-\infty}^{+\infty} (x - \mu_F)^2 F(x) dx = \sigma_F^2$$

 $\alpha=3$   $\beta=1$  a parameter  $\theta$  on F:  $\theta=mean/median$ 

## statistics reviewed

#### Gamma distribution:

$$x \sim \text{Gamma}(\alpha, \beta), \qquad \alpha > 0, \ \beta > 0$$
$$p(x) = \frac{\beta^{\alpha}}{\Gamma(\alpha)} x^{\alpha - 1} e^{-\beta x}, \qquad x > 0$$

Mean{Gamma( $\alpha, \beta$ )} =  $\alpha/\beta$ Var{Gamma( $\alpha, \beta$ )} =  $\alpha/\beta^2$ 

When  $\alpha \ge 1$  there is a single mode at  $x = (\alpha - 1)/\beta$ 

### $\alpha=3$ $\beta=1$ a parameter $\theta$ on F: $\theta=mean/median$

Let's try a simple example where we can see the "hidden" side of things, too.

Hidden side (population):

Statistic we are interested in happens to be (it could be anything):

 $\theta = \frac{\text{mean of distribution}}{\text{median of distribution}}$ 

```
sammedian = median(sample)
sammean = mean(sample)
samstatistic = sammean/sammedian
sammedian =
    2.6505
sammean =
                    How accurate is this?
    2.9112
samstatistic =
    1.0984
```

```
themedian = median(bigsample)
themean = mean(bigsample)
thestatistic = themean/themedian
themedian =
    2.6730
themean =
    2.9997
thestatistics =
    1.1222
              →θ parameter
```

## statistics reviewed

### Statistics or estimates

#### Definition

A statistic (also called estimates, estimators)  $\hat{\theta}$  is a function of  $\hat{F}$  or the sample **x**, e.g.:

$$\hat{\theta} = t(\hat{F})$$

or also written  $\hat{\theta} = s(\mathbf{x})$ .

### if $\hat{\theta}$ is the mean:

$$\hat{\theta} = t(\hat{F}) = \int_{-\infty}^{+\infty} x \, \hat{F}(x) dx$$
$$= \int_{-\infty}^{+\infty} x \, \frac{1}{n} \sum_{i=1}^{n} \delta(x - x_i) \, dx$$
$$= \frac{1}{n} \sum_{i=1}^{n} x_i$$
$$= s(\mathbf{x}) = \overline{x}$$

### Statistics or estimates

### if $\hat{\theta}$ is the variance:

$$\hat{\theta} = \int_{-\infty}^{+\infty} (x - \overline{x})^2 \hat{F}(x) dx$$
$$= \frac{1}{n} \sum_{i=1}^{n} (x_i - \overline{x})^2$$
$$= \hat{\sigma}^2$$

## statistics reviewed

## The Plug-in principle

#### Definition

The Plug-in estimate of a parameter  $\theta = t(F)$  is defined to be:

$$\hat{\theta} = t(\hat{F}).$$

The function  $\theta = t(F)$  of the probability density function F is estimated by the same function t(.) of the empirical density  $\hat{F}$ .

- $\overline{x}$  is the plug-in estimate of  $\mu_F$ .
- $\hat{\sigma}$  is the plug-in estimate of  $\sigma_F$

### Bootstrap samples and replications

#### Definition

A bootstrap sample  $\mathbf{x}^* = (x_1^*, x_2^*, \dots, x_n^*)$  is obtained by randomly sampling *n* times, with replacement, from the original data points  $\mathbf{x} = (x_1, x_2, \dots, x_n)$ .

Considering a sample  $\mathbf{x} = (x_1, x_2, x_3, x_4, x_5)$ , some bootstrap samples can be:

$$\mathbf{x}^{*(1)} = (x_2, x_3, x_5, x_4, x_5)$$
  
 $\mathbf{x}^{*(2)} = (x_1, x_3, x_1, x_4, x_5)$   
etc.

#### Definition

With each bootstrap sample  $\mathbf{x}^{*(1)}$  to  $\mathbf{x}^{*(B)}$ , we can compute a bootstrap replication  $\hat{\theta}^{*}(b) = s(\mathbf{x}^{*(b)})$  using the plug-in principle.

### How to compute Bootstrap samples

#### Repeat *B* times:

• A random number device selects integers  $i_1, \dots, i_n$  each of which equals any value between 1 and *n* with probability  $\frac{1}{n}$ .

2 Then compute 
$$\mathbf{x}^* = (x_{i_1}, \cdots, x_{i_n})$$
.

#### Some matlab code available on the web

See BOOTSTRAP MATLAB TOOLBOX, by Abdelhak M. Zoubir and D. Robert Iskander,

http://www.csp.curtin.edu.au/downloads/bootstrap\_toolbox.html

### How many values are left out of a bootstrap resample ?

Given a sample  $\mathbf{x} = (x_1, x_2, \dots, x_n)$  and assuming that all  $x_i$  are different, the probability that a particular value  $x_i$  is left out of a resample  $\mathbf{x}^* = (x_1^*, x_2^*, \dots, x_n^*)$  is:

$$\mathcal{P}(x_j^* \neq x_i, 1 \leq j \leq n) = \left(1 - \frac{1}{n}\right)^n$$

since  $\mathcal{P}(x_j^* = x_i) = \frac{1}{n}$ . When *n* is large, the probability  $(1 - \frac{1}{n})^n$  converges to  $e^{-1} \approx 0.37$ .

### The Bootstrap algorithm for Estimating standard errors

- Select B independent bootstrap samples x<sup>\*(1)</sup>, x<sup>\*(2)</sup>, ..., x<sup>\*(B)</sup> drawn from x
- 2 Evaluate the bootstrap replications:

$$\hat{ heta}^*(b) = s(\mathbf{x}^{*(b)}), \quad \forall b \in \{1, \cdots, B\}$$

Setimate the standard error  $se_F(\hat{\theta})$  by the standard deviation of the *B* replications:

$$\hat{\operatorname{se}}_B = \left[rac{\sum_{b=1}^B [\hat{ heta}^*(b) - \hat{ heta}^*(\cdot)]^2}{B-1}
ight]^{rac{1}{2}}$$

where  $\hat{\theta}^*(\cdot) = \frac{\sum_{b=1}^{B} \hat{\theta}^*(b)}{B}$ 

### Bootstrap estimate of the standard Error

#### Example A

From the distribution F:  $F(x) = 0.2 \mathcal{N}(\mu=1,\sigma=2) + 0.8 \mathcal{N}(\mu=6,\sigma=1)$ . We draw the sample  $\mathbf{x} = (x_1, \dots, x_{100})$ :

	7.0411	4.8397	5.3156	6.7719	7.0616	1
	5.2546	7.3937	4.3376	4.4010	5.1724	
	7.4199	5.3677	6.7028	6.2003	7.5707	
	4.1230	3.8914	5.2323	5.5942	7.1479	
	3.6790	0.3509	1.4197	1.7585	2.4476	
	-3.8635	2.5731	-0.7367	0.5627	1.6379	
	-0.1864	2.7004	2.1487	2.3513	1.4833	
	-1.0138	4.9794	0.1518	2.8683	1.6269	
	6.9523	5.3073	4.7191	5.4374	4.6108	
	6.5975	6.3495	7.2762	5.9453	4.6993	
i = ۲	6.1559	5.8950	5.7591	5.2173	4.9980	
	4.5010	4.7860	5.4382	4.8893	7.2940	
	5.5741	5.5139	5.8869	7.2756	5.8449	
	6.6439	4.5224	5.5028	4.5672	5.8718	
	6.0919	7.1912	6.4181	7.2248	8.4153	
	7.3199	5.1305	6.8719	5.2686	5.8055	
	5.3602	6.4120	6.0721	5.2740	7.2329	
	7.0912	7.0766	5.9750	6.6091	7.2135	
	4.9585	5.9042	5.9273	6.5762	5.3702	
	4.7654	6.4668	6.1983	4.3450	5.3261	

We have  $\mu_F = 5$  and  $\overline{x} = 4.9970$ .

### Bootstrap estimate of the standard Error

#### Example A

- B = 1000 bootstrap samples  $\{\mathbf{x}^{*(b)}\}$
- **2** B = 1000 replications  $\{\overline{x}^*(b)\}$
- Bootstrap estimate of the standard error:

$$\widehat{se}_{B=1000} = \left[\frac{\sum_{b=1}^{1000} [\overline{x}^*(b) - \overline{x}^*(\cdot)]^2}{1000 - 1}\right]^{\frac{1}{2}} = 0.2212$$

where  $\overline{x}^*(\cdot) = 5.0007$ . This is to compare with  $\hat{se}(\overline{x}) = \frac{\hat{\sigma}}{\sqrt{n}} = 0.22$ .

## Distribution of $\hat{\theta}$

When enough bootstrap resamples have been generated, not only the standard error but any aspect of the distribution of the estimator  $\hat{\theta} = t(\hat{F})$  could be estimated. One can draw a histogram of the distribution of  $\hat{\theta}$  by using the observed  $\hat{\theta}^*(b)$ ,  $b = 1, \dots, B$ .

## Bootstrap estimate of the standard error

### Definition

The ideal bootstrap estimate  $se_{\hat{F}}(\theta^*)$  is defined as:

$$\lim_{B\to\infty} \hat{\operatorname{se}}_B = \operatorname{se}_{\hat{F}}(\theta^*)$$

 $se_{\hat{F}}(\theta^*)$  is called a non-parametric bootstrap estimate of the standard error.

## Bootstrap estimate of the standard Error

#### How many B in practice ?

you may want to limit the computation time. In practice, you get a good estimation of the standard error for B in between 50 and 200.

#### Example A

В	10	20	50	100	500	1000	10000
sê <sub>B</sub>	0.1386	0.2188	0.2245	0.2142	0.2248	0.2212	0.2187

Table: Bootstrap standard error w.r.t. the number *B* of bootstrap samples.

### Bootstrap estimate of bias

#### Definition

The bootstrap estimate of bias is defined to be the estimate:

$$egin{aligned} \operatorname{Bias}_{\widehat{F}}(\widehat{ heta}) &= \mathbb{E}_{\widehat{F}}[s(\mathbf{x}^*)] - t(\widehat{F}) \ &= heta^*(\cdot) - \widehat{ heta} \end{aligned}$$

### Example A

В	10	20	50	100	500	1000	10000
$\mathbb{E}_{\hat{F}}(\overline{x}^*)$	5.0587	4.9551	5.0244	4.9883	4.9945	5.0035	4.9996
Bias	0.0617	-0.0419	0.0274	-0.0087	-0.0025	0.0064	0.0025

Table:  $\widehat{\text{Bias}}$  of  $\overline{x}^*$  ( $\overline{x} = 4.997$  and  $\mu_F = 5$ ).

### Bootstrap estimate of bias

B independent bootstrap samples x<sup>\*(1)</sup>, x<sup>\*(2)</sup>, ..., x<sup>\*(B)</sup> drawn from x
 Evaluate the bootstrap replications:

$$\hat{ heta}^*(b) = s(\mathbf{x}^{*(b)}), \quad \forall b \in \{1, \cdots, B\}$$

O Approximate the bootstrap expectation :

$$\hat{\theta}^{*}(\cdot) = \frac{1}{B} \sum_{b=1}^{B} \hat{\theta}^{*}(b) = \frac{1}{B} \sum_{b=1}^{B} s(\mathbf{x}^{*(b)})$$

the bootstrap estimate of bias based on B replications is:

$$\widehat{\operatorname{Bias}}_B = \hat{\theta}^*(\cdot) - \hat{\theta}$$

305

We previously compared bootstrap-from-sample to bootstrap-from-population. **More relevant, let's compare boostrap-from-sample to sample-the-posterior:** 

- We could increase number of samples of posterior, and of bootstrap, to make both curves very smooth.
  - the histograms would not converge to each other!
- We could increase the size of the underlying data sample
  - from 20 (x,y) values to infinity (x,y) values
  - the histograms would converge to each other (modulo technical assumptions)
- For finite size samples, each technique is a valid answer to a different question
  - Frequentist: Imagining repetitions of the experiment, what would be the range of values obtained?
    - And. conservatively, I shouldn't expect my experiment to be better than that, should I?
  - Bayesian: For exactly the data that I see, what is the probability distribution of the parameters?
    - Because maybe I got lucky and my data set really nails the parameters!

Note that sampling the posterior "honors" the stated measurement errors. Bootstrap doesn't. That can be good!

bootstrap

 $2x_1$ 

 $x_1 + x_2$ 

Suppose (very toy example) the "statistic" is

 $s = x_1 + x_2$ 

then the posterior probability is

$$P(s) \propto \exp\left[-\frac{1}{2} \frac{(s - x_1 - x_2)^2}{\sigma_1^2 + \sigma_2^2}\right]$$

#### Note that this depends on the $\sigma$ 's!

The bootstrap (here noticeably discrete) doesn't depend on the  $\sigma$ 's. In some sense it estimates them, too.

So, if the errors were badly underestimated, sampling the posterior would give too small an uncertainty, while bootstrap would still give a valid estimate.

If the errors are right, both estimates are valid. Notice that the <u>model</u> need not be correct. Both procedures give estimates of the statistical uncertainty of parameters of even a wrong (badly fitting) model. But for a wrong model, your interpretation of the parameters may not mean anything!

sample posterior

 $2x_2$
